PREFACE

A considerable amount of data were generated during the RMA Emission Factors Development Project. In developing a report format for this study, the program discussions, emissions factor data package, statistical data, and program protocols were identified as requiring segregated volumes to serve the needs of a diverse group of readers. This information is organized and presented in the following volumes:

- Volume 1 Emission Factor Program Results
- Volume 2 Project Data
- Volume 3 Test Procedures and Protocols

The Volume 2 Project Data Report presents a comprehensive, detailed summary of all pertinent process and emissions data generated in this program. Specifically, data contained herein have been organized by individual rubber manufacturing process. Each section presents the process data, a summary of emission factors by pollutant group and rubber or tire type, and detailed emission rates of speciated pollutants.

The processes evaluated and reported in this data package are:

- Internal Mixing and Milling
- Extrusion
- Autoclave Curing
- Calendering
- Hot Air Oven Curing
- Warmup Mill
- Tire Press Curing
- Platen Press Curing
- Grinding

The pollutant emissions evaluated and reported with emission factors are:

- Total Volatile Organic Compounds
- Ozone Precursors
- Sulfur Compounds
- Particulate Matter
- Amines
- Speciated Volatiles
- Speciated Semivolatiles
- Polycyclic Organic Matter
- Trace Metals

The rubber-specific information contained in this report is based upon generic rubber compounds, company-specific tire types, and normal production rubber types. The generic rubber compounds are summarized in Section 1, along with their compounding recipes. The reader should refer to this section to obtain the identification number assigned to each rubber compound evaluated in this program. This compound number is used throughout this report series to identify the individual rubber types.

Due to the confidentiality of the company-specific tire types, information on individual tires is

not presented. Rather, tire-specific information is grouped and presented by press mold size. The tires cured in the tire press were of two size ranges, 195 and 205. These were selected to represent a suitable cross section of tire sizes manufactured in the U.S. Truck tires were not within the scope of this program.

FORMALDEHYDE EMISSIONS TEST PROGRAM

Background

Formaldehyde emissions were measured during the platen press curing of two generic rubber compounds, Compound No. 1 (Tire Inner Liner) and Compound No. 7 (Tire Bladder). The platen press was used to simulate processing of the compounds at a temperature of 340° F, typical of non-productive mixing and curing operations. The rubber compounds were uncured formulations mixed on a small Banbury in late 1994 and stored at TRC's Lowell facility since that time.

The platen press curing process is a general approach to pressure-curing engineered rubber products in molds. The platen press was used in this testing to simulate higher temperature conditions for maximum formaldehyde off-gassing. Emissions from the platen presses were controlled using an exhaust hood and duct.

The platen press used in this program was manufactured by Pasadena Hydraulics, Inc. of Pasadena, CA and provided for the test program by the Goodyear Tire and Rubber Company. Testing was conducted at TRC's Lowell, MA facility. Emission rates were developed based on: pounds of pollutant emitted per hour (lbs/hr) and pounds emitted per pound of rubber (lbs/lb rubber) cured.

Sampling Approach

During this program, the platen press was operated at a temperature of 340° F and pressures of 30 tons for the first 3 minutes and 20 tons for the second 3 minutes. Nine samples of approximately 50 grams each were cured for each rubber type. Each 50-gram tab of rubber was placed directly onto the lower plate and pressed into a "pancake" approximately 185 mm in diameter and 1 mm thickness. The cooldown period lasted for 6 minutes when the cured samples were removed from the press and left inside the enclosure. Emissions were contained by an exhaust hood and flexible Tyvek sheeting, and exhausted by a single 5-inch duct and blower.

Sampling was conducted in accordance with Method TO-11 using dinitrophenyl-hydrazine (DNPH)-impregnated silica gel in sampling cartridges. Exhaust gas from the platen press ductwork was drawn through the cartridge at a known rate (200 mL/min.) for a 2-hour period. During this sampling period, nine tabs of the desired rubber compound were pressed. One integrated sampling event was conducted for each rubber compound. A total of 1.04 lbs of rubber was pressed for each integrated sample.

Analytical Summary

Analyses of two field samples and one field blank were conducted in accordance with Method TO-11. Analysis was by HPLC using a Hewlett Packard ODS Hyersil column. The

laboratory also prepared and analyzed sets of Laboratory Spikes and Spike Duplicates and Method Blanks. Lab Spike and Spike Duplicate recoveries were 86 and 82 percent, respectively.

Emissions Results

The results of the emissions testing are shown in Table 1. The formaldehyde concentrations were very low, but detectable. All results were less than the lowest calibrator, so the reported concentrations are estimated based on extrapolation of the standard curve. A comparison of formaldehyde emissions from the two rubber compounds yields very similar results, although Compound No. 1 emissions were slightly higher. Table 2 presents the recipes for these two rubber formulations.

An emission factor for formaldehyde emissions from Compounds 1 and 7 was developed and is reported in Table 1. This factor represents the pounds of formaldehyde emitted for every pound of rubber compound processed in this temperature range. Please note that for any given process, the emission factor user should be aware that there will be differences in formaldehyde release rates depending on the amount of exposed rubber surface area, the process type, and the rubber temperature.
