

Pesticide Fact Sheet

Name of Chemical: Iodomethane
Reason for Issuance: New Chemical Registration
Year Issued: 2007

DESCRIPTION OF CHEMICAL

Generic Name: TM-425 Technical Iodomethane: CH₃I

Common Name: None recognized

Trade Name: Midas Bronze, Midas Gold, Midas 98:2, Midas 50:50,
Midas 33:67, and Midas 25:75

EPA Chemical Code: 000011

Chemical Abstracts
Service (CAS) Number: 74-88-4

Year of Initial Registration: 2007

Pesticide Type: Fumigant

Chemical Class: Alkyl Iodide

Registrant: Arysta LifeScienc North American Corporation
15401 Weston Parkway, Suite 150
Cary, North Carolina 27513

Chemical Structure:

USE PATTERNS AND FORMULATIONS

Pests/Application Sites: Iodomethane is a pre-plant biocide used to control insects, plant parasitic nematodes, soil borne pathogens, and weed seeds. The compound is registered for use as a preplant soil treatment for field grown strawberries, peppers, tomatoes, stone fruits, tree nuts, grape vines, ornamentals and turf and nursery grown strawberries, stone fruits, tree nuts, and conifer trees.

Types of Formulations: Iodomethane is a liquid under pressure, and is marketed in the following formulations:

| Table 1: Product Names | Percentage of Iodomethane | Percentage of Chloropicrin |
|-------------------------------|----------------------------------|-----------------------------------|
| Iodomethane Technical | 99.8% | ---- |
| Midas 98:2 | 97.8% | 1.99% |
| Midas 50:50 | 49.9% | 49.75% |
| Midas EC Bronze | 49.9% | 44.78% |
| Midas 33:67 | 32.93% | 66.67% |
| Midas EC Gold | 32.93% | 61.69% |
| Midas 25:75 | 24.95% | 74.63% |

Application Methods: The application methods are as follows: Raised bed – Shank Injection; Broadcast/Flat Fume – Shank Injection; Auger Probe - Deep Injection; and Raised Bed - Drip Application. Applications via raised bed and broadcast/flat fume are covered with a tarp for a minimum of five days and with a minimum of seven days before planting occurs. For buried drip tape application, ten days must elapse before planting.

- Application Rates: The application rates for Iodomethane are as follows:
- Raised bed – Shank Injection – 75 to 175 lbs. active ingredient (a.i.)/treated acre
 - Raised Bed – Drip Application – 100 – 175 lbs. a.i./treated acre
 - Broadcast/Flat Fume – 100 to 175 lbs. a.i./acre
 - Deep Auger Probe Injection – 0.5 to 2 lbs. a.i./injection site

SCIENCE FINDINGS

I. SUMMARY OF PHYSICAL AND CHEMICAL PROPERTIES

| Table 2: Physical-Chemical Properties of Iodomethane Technical – CH₃I | |
|---|--|
| Parameter | Comment |
| Color | Clear to light yellow |
| Physical State | Liquid |
| Odor | Ether-like |
| Molecular Weight | 141.94 g/Mol |
| Molecular Formula | CH ₃ I |
| UV Absorption | 2.5 absorbance units (maximum) at ca. 200 nm, with a smaller peak (0.25 au) at ca. 250 nm) |
| Melting Point | -66.5 ⁰ C |
| Boiling Point | 42.4 ⁰ C |
| Specific Gravity | 2.8 at 20 ⁰ C |
| Henry's Law Constant | 5.23 x10 ⁻³ atm-m ³ /mole |
| Partition Coefficient (Octanol/Water, log K _{ow}) | 1.51 – 1.69 |
| Water Solubility | 1420 mg/L at 25 ⁰ C |
| Density | 2.28 g/mL at 20 ⁰ C |
| Vapor Density (Air = 1) | 4.9 |
| Vapor Pressure | 405.9 mm Hg at 25 ⁰ C |

II. SUMMARY OF TOXICITY DATA

HUMAN HEALTH

A. Acute Toxicity

| Table 3: Acute Toxicity Summary for Iodomethane Technical | | |
|--|---|--------------------------|
| Study Type | Results | Toxicity Category |
| Acute Oral (rat) | LD ₅₀ > 79.8 mg/kg (males) > 131.9 mg/kg (females) | II |
| Acute Oral (mouse) | LD ₅₀ > 155 mg/kg (males) > 214 mg/kg (females) | II |
| Acute Dermal (rat) | LD ₅₀ > 2000 mg/kg (both sexes) (limit test) | III |
| Acute Inhalation (rat) | LD ₅₀ > 4 mg/L (both sexes) | IV |
| Primary Eye Irritation (rabbit) | Corrosive: Corneal opacity and bulging, conjunctivitis, iritis, corneal neo-vascularization and sloughing of epithelium, blanching of nictitating membrane, | I |
| Primary Skin Irritation (rabbit) | Well defined erythema extending beyond test sites, blanching, and light-severe edema | II |
| Dermal Sensitization | Non-sensitizer | N/A |

| Table 4: Acute Toxicity Categories for MIDAS 98:2, MIDAS 50:50, and MIDAS™ 25:75 | | |
|---|---|---|
| Study Type/Findings | Toxicity Categories for Midas 50:50, Midas 33:67, Midas 25:75, Midas Gold and Midas Bronze | Toxicity Categories for Midas 98:2 |
| Acute Oral Toxicity | II | II |
| Acute Dermal Toxicity | III | III |
| Acute Inhalation Toxicity | II | IV |
| Primary Eye Irritation | I | I |
| Primary Dermal Irritation | I | II |
| Dermal Sensitization | Positive for sensitization | Positive for sensitization |

B. Subchronic Inhalation Toxicity

In a subchronic inhalation toxicity study, rats were exposed via whole-body inhalation for 6 hours/day, 5 day/week for 13 weeks at analytical concentrations of 0, 5, 21, or 70 ppm (0, 0.029, 0.12, or 0.41 mg/L/day). Ten rats/sex/concentration were sacrificed after 4 weeks, and the remaining 10 rats/sex/concentration were sacrificed after 13 weeks. There were no effects of treatment on mortality, ophthalmology, urinalysis, hematology, organ weights, or gross pathology. The systemic LOAEL for this study is 70 ppm based on initial decreases in body weights, body weight gains, and food consumption (males). The NOAEL is 21 ppm (HEC = 3.8 or 15.8 ppm for non-occupational and occupational risk assessments, respectively). The port-of-entry LOAEL is 70 ppm based on degeneration of the olfactory epithelium. The NOAEL is 21 ppm (HEC = 4.5 or 5.8 ppm for non-occupational and occupational risk assessments, respectively).

C. Developmental Toxicity

In a developmental toxicity study, groups of 24 female New Zealand White rabbits were dynamically exposed to iodomethane vapor in whole-body inhalation chambers at analytical concentrations of 0, 2, 10, or 20 ppm (0, 0.012, 0.058, or 0.12 mg/L/day) six hours per day on gestation days (GDs) 6 through 28. The maternal NOAEL is 20 ppm; no maternal LOAEL was identified. The developmental toxicity LOAEL is 20 ppm based on increased fetal losses and decreased fetal weights (\downarrow 20%). The developmental toxicity NOAEL is 10 ppm (HEC = 7.4 or 23 ppm for non-occupational and occupational risk assessments, respectively).

In a developmental toxicity study, iodomethane was administered via the inhalation route (whole body) to 24 New Zealand White rabbits/group at concentrations of 0 or 20 ppm during GD 6-28 (Control and Group 2), GD 6-14 (Group 3), GD 15-22 (Group 4), GD 23-24 (Group 5), GD 25-26 (Group 6), or GD 27-28 (Group 7) for 6 hours/exposure day. This study was not intended to fulfill the guideline requirement or establish NOAELs and LOAELs but rather was conducted to determine the critical period of exposure during gestation that resulted in fetal loss as observed in a previously evaluated guideline developmental toxicity study in rabbits.

D. Acute Neurotoxicity

In an acute neurotoxicity study in rats, iodomethane was administered *via* the inhalation route (whole body) to 12 rats/sex/group at concentrations of 0, 27, 93, or 401 ppm for 6 hours. The NOAEL is 27 ppm (HEC = 10 ppm for both bystander and occupational risk assessments). The LOAEL is 93ppm based on clonic convulsions, decreased body temperatures, and decreased motor activity.

E. Carcinogenicity

The Agency evaluated the rodent bioassays and mechanistic data available for iodomethane. Evidence of carcinogenicity in the iodomethane database manifested as an increased incidence of thyroid follicular cell tumors observed in both the Inhalation Chronic Toxicity/Carcinogenicity Study in Rats and the Carcinogenicity Study in Mice. The Agency concluded that the key event

influencing the thyroid tumor response is the sustained stimulation of cell proliferation by TSH, consistent with the increase in thyroid follicular cell tumors only. Based on the evidence that rats are substantially more sensitive than humans to the development of thyroid follicular cell tumors in response to thyroid hormone imbalance, the Agency classified iodomethane as ‘not likely to be carcinogenic to humans in the absence of altered thyroid hormone homeostasis’. The dose-response for cancer effects was considered in the risk assessments and the exposures expected from this use are well below those that would cause thyroid effects leading to cancer.

F. Mutagenicity

Mutagenicity was not demonstrated in the following tests: Bacterial Reverse Mutation Test; *In Vitro* Mammalian Cell Mutation Test in Chinese Hamster Ovary Cells; and a *In Vitro* Micronucleus Assay in Mice. However, in the *In Vitro* Chromosomal Aberration in Chinese Hamster Ovary Assay, iodomethane was positive for induction of structural chromosome aberrations (clastogenesis), but negative for induction of numerical aberrations in CHO cells.

G. Metabolism

A rat metabolism study comparing absorption after oral and inhalation administration indicated that iodomethane is quickly absorbed through both routes of exposure. In contrast, the elimination profile indicates that excretion of ¹⁴C-labeled iodomethane is biphasic with an initial half-life of 5-7 hours and a terminal half-life of approximately 116-136 hours.

H. Mechanistic Data

An extensive mechanistic data set, as well as a physiologically based pharmacokinetic (PBPK) model, are available for iodomethane. These data and model constitute a sophisticated effort to better characterize the toxicity profile for this compound in terms of developmental toxicity, respiratory tract lesions, and thyroid hormone perturbations identified as the critical effects of iodomethane exposure. In addition, the use of a PBPK model that takes into consideration the toxicokinetic aspect of iodomethane exposure enables the Agency to use chemical-specific parameters to determine the most appropriate dose metric and internal dose in calculating human equivalent concentrations (HECs) instead of the default inputs used in the Agency’s Reference Concentration (RfC) methodology. The Agency has reviewed these data and their usefulness to calculate human equivalent concentrations (HECs) based on chemical-specific data. In general, the model and the mechanistic studies used to provide its inputs are considered adequate and their results have been incorporated into this risk assessment.

I. Observational Human Data

The Observational Human Study was not intended to provide NOAELs/LOAELs for risk assessment purposes but rather to better characterize the typical physiological distribution of inorganic iodide between the fetus and its mother (a critical parameter in the iodomethane PBPK model). In the study, maternal and cord blood samples (cord blood was used as a surrogate for fetal blood) were collected from 92 mothers delivering at full-term (37-41 weeks gestation) and 31 mothers delivering pre-term (29 to < 37 weeks gestation). It is important to note that **study participants were not exposed to any test article** and that the samples used in this study were

aliquots of samples routinely collected during labor and delivery.

The Agency has reviewed these data and its usefulness to calculate human equivalent concentrations (HECs) based on chemical-specific data. The mechanistic and observational human studies were intended to either define the dose metric or provide compound-specific inputs for the PBPK model. To derive HECs using the PBPK model, internal dose metrics are predicted for the test species in which the adverse effect occurred and then the version of the PBPK model for humans is used to predict the inhalation exposure concentration (HEC) that would result in the same dose metric as in the animal. The model is a sophisticated effort to describe the kinetics of methyl iodide following inhalation exposure and the kinetics of iodide as a metabolite. It describes nasal tract dosimetry and glutathione (GSH) depletion in the rat to evaluate nasal toxicity, iodide kinetics in the pregnant rabbit to address developmental toxicity, and distribution of methyl iodide to the brain to describe the dose metric for neurotoxic effects. The model has also been parameterized for the human and Monte Carlo analyses were performed to describe human variability. The review was carried out using the framework described in Clark et al., 2004. The results of the evaluation were described focusing on the rat and human nasal modeling, the rabbit and human pregnancy modeling, the rat and human neurotoxicity model, modeling human variability, and model documentation. The strengths and limitations of the modeling were identified. The nasal modeling for rat and human was concluded to be adequate to estimate a human equivalent concentration. Selection of the appropriate degree of GSH depletion to predict nasal olfactory toxicity was dependent on additional factors beyond the PBPK/PD modeling, including judgments about the relationship of this measure with toxicity and the linkage of the time-course of exposure concentrations with the prediction of GSH depletion. The pregnancy modeling was found to be adequate to estimate a range of human equivalent concentrations. The human variability analysis was considered to provide perspective on the default value of 3 to address human pharmacokinetic variability. Similarly, the neurotoxicity model was found to be adequate to estimate a human equivalent concentration based on iodomethane brain concentrations. In general, the model and mechanistic studies used to provide its inputs were considered adequate and their results have been incorporated into the Agency's risk assessment.

II. TOXICITY ENDPOINTS

Based on the toxicity profile and the major exposure routes of iodomethane, endpoints have been selected for the residential/bystanders and occupational human health risk assessments. The Agency used the reference concentration (RfC) methodology along with a PBPK model to derive the human equivalent concentration (HEC) for inhalation exposures. Under the RfC methodology and the PBPK model approach, endpoint selection was based on the HECs which were derived from the NOAELs in selected studies. The specific concentrations and endpoints for the exposure scenarios are summarized below:

A. Acute Inhalation - Non-Occupational (Bystander) and Occupational (Handler)

Three critical endpoints have been identified: nasal histopathology in the subchronic inhalation toxicity study in rats, the fetal losses in the developmental toxicity study in rabbits, and neurotoxicity in rats. An HEC of 4.5 or 5.8 ppm was selected (bystander and occupational risk assessments, respectively) from the NOAEL of 21 ppm based on degeneration of the olfactory epithelium. For the developmental endpoint, the Agency selected an HEC of 7.4 or 23 ppm (bystander and occupational risk assessments, respectively) from the NOAEL of 10 ppm based on fetal losses and decreased fetal weights in a developmental toxicity study in rabbits at the LOAEL of 20 ppm. The HEC for the neurotoxicity endpoint is 10 ppm (for both bystander and occupational exposures) based on clonic convulsions, decreased body temperature, and decreased motor activity.

B. Short-, and Intermediate-term Inhalation

1. Non-occupational (Bystander)

An HEC of 1.25 ppm from the NOAEL of 5 ppm was selected based on decreased pup weight and weight gain, decreased thymus weights, and delays in vaginal patency acquisition seen in the multigeneration reproduction toxicity study at the LOAEL of 20 ppm.

2. Occupational (Handler)

An HEC of 3.7 ppm was selected from the NOAEL of 21 ppm based on minimal to mild degeneration of the olfactory epithelium seen at the LOAEL of 70 ppm in the subchronic inhalation toxicity study in rats.

C. Long-term Inhalation

1. Non-occupational (Bystander)

An HEC of 0.89 ppm from the NOAEL of 5 ppm was selected based on increased incidence of salivary gland squamous cell metaplasia seen at the LOAEL of 20 ppm observed in a rat chronic toxicity/carcinogenicity study.

2. Occupational (Handler)

An HEC of 3.75 ppm from the NOAEL of 5 ppm was selected based on increased incidence of salivary gland squamous cell metaplasia seen at the LOAEL of 20 ppm observed in a rat chronic toxicity/carcinogenicity study.

III. UNCERTAINTY FACTOR

Iodomethane has been classified as a non-food use pesticide. Consequently, this chemical is not subject to the FQPA (1996). When conducting inhalation risk assessments, the magnitude of the

UFs applied is dependent on the methodology used to calculate risk. The risk assessment was based on the RfC methodology developed by the Office of Research and Development (ORD) and the PBPK model developed by the registrant for the derivation of inhalation reference concentrations (RfCs) and human equivalent concentrations (HECs) for use in margin of exposure (MOE) calculations. Since both of these approaches take into consideration the pharmacokinetic (PK) but not pharmacodynamic (PD) differences between test species and humans, the UF for interspecies extrapolation was reduced to 3X while the UF for intraspecies variation was retained at 10X. Thus, when using the RfC methodology, the overall UF is customarily 30X.

IV. RESIDUE CHEMISTRY

Plant metabolism studies on strawberries and tomatoes showed that iodomethane is extensively metabolized and incorporated into plant constituents, primarily carbohydrates. Iodide levels in the raw commodities were comparable to background levels found in control samples. Finite residues of toxicological concern are highly unlikely, and the pre-plant fumigant application of iodomethane is considered to be a non-food use and tolerances are not needed.

V. FOOD QUALITY PROTECTION ACT CONSIDERATIONS

Since dietary exposure is not expected and there are no residential uses proposed for iodomethane, the provisions of the Food Quality Protection Act (FQPA) of 1996. An aggregate risk assessment was not conducted because inhalation is the only route of exposure.

VI. HUMAN EXPOSURE/RISK SUMMARY

A. Dietary Exposure and Risk

Iodomethane is considered a non-food use chemical, and the Agency concluded tolerances are not required for iodomethane. As a result, a risk assessment was not conducted for this exposure scenario.

B. Estimated Drinking Water Concentrations

Based on environmental fate data, the residual contents in soils, and Tier I and II models estimated concentrations, the Agency does not expect iodomethane to adversely impact ground water or surface water. Tier II PRZMS for surface water and Tier I SCIGROW for ground water were used to estimate iodomethane concentrations. These concentrations were in the nanograms per Liter (ng/L), and parts per trillion range. The Agency conducted a qualitative drinking water assessment and determined that no risk are expected from this potential exposure.

C. Dermal Exposure and Risk

In the general population, dermal exposure to iodomethane is not expected. Dermal exposure of workers to iodomethane of any significance is not expected based on the delivery systems used

(e.g., soil injection or drip irrigation), packaging (i.e., pressurized cylinders), and emission reduction technologies (e.g., tarping). The high vapor pressure of iodomethane also makes significant dermal exposure unlikely and quantifying any potential low level exposures very difficult. Therefore, a quantitative dermal exposure assessment was not conducted.

D. Acute Inhalation Exposure and Risk

The Agency conducted a quantitative acute exposure assessment. Because of iodomethane's anticipated use pattern, its emission profile and the nature of its toxicity, the Agency believes that the acute exposure assessment is protective for other durations of exposure.

Releases of fumigants such as iodomethane can be categorized in two distinct manners. Ambient air levels from multiple area sources could occur from many applications in a region (e.g., several farms in a specific valley), or alternatively, off-gassing of iodomethane can occur from a known area source (e.g., a treated agricultural field).

1. Non-Occupational (Bystander) Exposure and Risk - Ambient Air

Exposures from ambient sources were qualitatively evaluated based on physical-chemical properties and environmental fate characteristics of iodomethane. Ambient air monitoring data were not available since iodomethane is not currently widely used. Ambient air exposures could potentially occur in proximity to agricultural areas where there is significant use during a particular growing season on a regional basis (e.g. in coastal areas of California during field fumigation prior to strawberry growing season). However, the Agency does not believe that ambient air exposures to bystanders are likely to be a significant concern based on a comparison of the characteristics of iodomethane with those of methyl bromide and the ambient air monitoring data available for methyl bromide.

2. Non-Occupational (Bystander) and Occupational (Handler Exposure and Risk – Off-gassing

To estimate the bystander and occupational exposure and risk resulting from the off-gassing of a treated agricultural field, the Agency used the Probabilistic Exposure and Risk model for Fumigants (PERFUM model). The PERFUM model uses emissions data from field volatility studies and five years of meteorological data to calculate downwind air concentrations from a treated field. PERFUM analyses were completed for field sizes ranging from 1 to 40 acres using weather data representative of the geographic locations where major iodomethane use is anticipated and emissions data from representative locations.

In determining the buffer zone distances to require for iodomethane the following tables were used to analyze the risk. Three types of analysis were considered as follows: (1) Table 5 (Table 12 in the risk assessment) provides buffer distances (in meters) where target concentrations (MOE=30) are achieved, for example the 95th percentile on the maximum distance distribution; (2) Table 6 shows the percentile of exposure for pre-selected buffer

distances (in meters and feet) and; Table 7 uses distributions of air concentrations at a specific buffer distance (in feet) from the field edge to calculate Margins of Exposure (MOEs) where the target MOE=30.

These analyses demonstrate risks associated with a range of input factors including: (1) Flux – High emissions for each application type; (2) Weather – Stations that have low, medium and high results; (3) Field size – Largest field size for each buffer distance range (e.g. for the range of 20 to 40 acres, the estimates are for 40 acres); (4) Application rate – Maximum rate was used (Note: The risk picture is similar for all rates because the tables are scalable) and: (5) Endpoints – Risk estimates for three distinct endpoints were examined (nasal lesions, neurotoxicity, and fetal loss).

Buffer zones to be required for iodomethane were chosen by examining this type of output in an iterative fashion. The buffer zone distances required for iodomethane are those shown in Table 4. These distances were determined to provide adequate margins of safety based on the magnitude of the MOEs considering the reasonable worst case represented by the combination of the highest flux and weather in the analysis (Bradenton/Guadalupe). It was also noted that because of the high percentiles of exposure being considered, there is a diminished change in the MOEs as buffer distances increase.

Table 5: Buffer Distances (in meters) Where Target Concentrations (MOE=30) Are Achieved

3. Occupational Exposure and Risk

Occupational exposure and risks exceed the Agency’s level of concern for some workers (tractor drivers, co-pilots, tarp monitors, and shovelers) when no respiratory protection is used. These risks are sufficiently reduced with respiratory protection to levels below the Agency’s level of concern. Respirators will be required for all workers with unacceptable risks. However, tractor drivers and co-pilots will have the option of using a fan/air duct system that meets certain specifications in lieu of a respirator. Worker exposure five days after application, even without any respiratory protection, does not exceed the Agency level of concern.

E. Aggregate Exposure and Risk

The physical/chemical characteristics, the environmental fate data, and results of metabolism studies in plants assure that there is no reasonable expectation of finite residues in or on food and drinking water when iodomethane is applied according to label directions. Therefore, iodomethane does not require food tolerances, is considered to be a ‘non-food use’ chemical, and

is not subject to the amendments to the Federal Food, Drug, and Cosmetic Act (FFDCA) promulgated under the Food Quality Protection Act (FQPA) of 1996, and an aggregate risk assessment is not required.

F. Cumulative Risk

Unlike other pesticides for which the Agency has followed a cumulative risk approach based on a common mechanism of toxicity, the Agency has not made a common mechanism of toxicity finding as to iodomethane and any other substances and iodomethane does not appear to produce a toxic metabolite produced by other substances. For the purposes of this action, therefore, the Agency has not assumed that iodomethane has a common mechanism of toxicity with other substances.

ENVIRONMENTAL FATE AND EFFECTS

A. ENVIRONMENTAL FATE

The high vapor pressure and low affinity for sorption on soil of iodomethane suggest that volatilization is the most important environmental route of dissipation. Field data from iodomethane applied via broadcast shank injection to a bare-ground plot and covered simultaneously with a standard plastic tarpaulin over the treated plot suggests that 54 to 80

percent of iodomethane dissipated to the atmosphere before the tarpaulin was removed. Once volatilized into the atmosphere, iodomethane degrades rapidly due to direct photolysis and the estimated atmospheric residence time is less than 12 days.

Field dissipation data show that no residual iodomethane was detected at the end of the field study period at any site tested. Even if any iodomethane exposure should occur in the surface water, a low Henry's Law constant suggests rapid volatilization of iodomethane to the atmosphere. Tier II PRZM/EXAMS and Tier I SCIGROW were used to estimate iodomethane concentrations in surface water and ground water, respectively. Based on environmental fate data, the residual contents in soils, and Tier I and II model estimated concentrations, the Agency does not expect iodomethane to adversely affect ground water or surface water. However, since iodomethane is soluble in water, there is the possibility of leaching to ground water if slicing or removal of the tarpaulin coincides with, or is followed soon by, a rain event. Consequently, the Agency is requiring cautionary language on the label prohibiting the slicing or removal of the tarpaulin if it is raining or if rain is expected within 48 hours after treatment.

B. ECOLOGICAL EFFECTS

1. Aquatic Exposure and Risk

The Agency does not consider iodomethane to pose an acute or chronic risk to fish and aquatic invertebrates because of low potential of iodomethane runoff from the tarped post application sites to surface water bodies. The low octanol/water partition coefficient indicates that

iodomethane is not likely to bioconcentrate in tissues of aquatic organisms. Comparing the highest acute aquatic EEC to the acute toxicity value for the most sensitive test species (*D. magna*) produces a maximum risk quotient of 0.0017. This risk quotient is well below the lowest acute aquatic Level-of-Concern (LOC) of 0.05 for endangered species. The Agency also believes that the low Henry's Law Constant of iodomethane suggests that chronic exposures to aquatic invertebrates and fish are not likely to occur.

2. Terrestrial Exposure and Risk

The primary route of exposure of nontarget terrestrial organisms to iodomethane is from inhalation of air residues near the treated sites. Estimated air concentrations are the highest on the application day with estimated concentrations ranging from 0.987 ppm at 30 cm above the tarp and up to 0.453 ppm at 80 cm above the tarp. These values are estimated flux values based on cumulative charcoal tube residues collected following an application of 242 lb. a.i./acre.

The avian acute inhalation LC₅₀ based on a four-hour exposure of bobwhite quail is 395 ppm which is 400X the peak estimated residues. Therefore, it does not appear that there is a substantial risk of acute lethality to birds, even if they fly above or land on the tarp on the day of application. At the lowest test concentration of 344 ppm, sublethal effects were seen and included ataxia, gasping and rales. Given that a No Effect Level was not obtained, it is not possible to say with certainty that there would be no sublethal effects at the expected maximum exposure levels. However, given that the lowest test level was approximately 350X greater than the expected maximum residues, it is quite possible that there would be no sublethal effects as well. Iodomethane is also a short-lived chemical (direct photolysis, ≤ 11.5 days) in the atmosphere; therefore, there is low potential for chronic risk to birds and mammals.

Dispersion and photolysis of iodomethane will likely result in birds and wild mammals being exposed to substantially lower residues and risk than those immediately above the tarp on the day of application. Mammals appear to be less acutely sensitive than birds to iodomethane. The reported mammal acute inhalation LC₅₀ is 4.0 mg/L (689 ppm). The inhalation maternal NOAEL in a developmental toxicity study with female New Zealand White rabbits is 10 ppm which is above the acute wild mammal exposure and thus substantial risk is not expected. It is not expected that there would be any major use by wildlife of the soil under the tarp. However, some wildlife (e.g. amphibians) may possibly seek dark, warm, moist areas such as the area under a tarp which might result in a lethal exposure.

Iodomethane is phytotoxic and given the label statement referencing the potential to damage caused by drift to other plants or crops, iodomethane may be hazardous to plants off-site. However, based in part on a prior draft biological opinion from the U.S. Fish and Wildlife Service for tarped uses of methyl bromide, the Agency does not presently have a concern for the proposed tarped uses of iodomethane for endangered species, including endangered plants.

C. GLOBAL WARMING AND OZONE DEPLETION POTENTIAL

Once volatilized, iodomethane degrades rapidly in the lower atmosphere via direct photolysis and lasts in the atmosphere less than twelve days, as compared with two years for methyl bromide. Therefore, iodomethane is unlikely to reach upper atmosphere to have an impact

upon the ozone layer. The estimated ozone depletion potential (ODP) for iodomethane is 0.029, much lower than the 0.65 for methyl bromide. Iodomethane’s ODP of 0.029 also is well below the 0.20 level of Class I ozone depleters specified under Title VI, Section 602 of the Clean Air Act. However, global uncertainty on volatilization rates, residence time in soil, photolytic degradation of iodomethane, and the removal of iodine radicals from the troposphere means that the possibility of detrimental effects of iodomethane on ozone layer and a contribution to global warming can not be excluded entirely.

SUMMARY OF REGISTRATION DECISION

A. CONDITIONS OF REGISTRATION

The registrant has agreed in writing to the following conditions for registration: (1) to provide a training/stewardship program using criteria agreed upon with the Agency; (2) to satisfy any additional data requirements and to add any additional risk mitigation as required by the Agency once the Agency makes a decision for the soil fumigant group and to submit label amendments for each iodomethane product within the same timeframe imposed on other soil fumigant registrants for similar label amendments. In addition, the registration will be time- limited for one year.

B. Risk Mitigation

1. End use products are classified as restricted use.
2. Buffer zones are specified on product labels. The buffer zones provide flexibility based on several factors such as application rate; field size; application method, type of tarp, and soil characterization. The following table provides examples of the required buffer zones:

| Application Rate (lb a.i./treated acre) | Size Of Contiguously Treated Area (acres) | Buffer Zone Distance in Feet If HDPE* or LDPE** Tarps are Used |
|---|---|--|
| 175 (max) | >20 to 40 | 500 |
| | >10 to 20 | 300 |
| | >5 to 10 | 100 |
| | Up to 5 | 50 |
| 131 (75%) | >20 to 40 | 375 |
| | >10 to 20 | 225 |
| | >5 to 10 | 75 |

| | | |
|----------|-----------|-----|
| | Up to 5 | 40 |
| 88 (50%) | >20 to 40 | 250 |
| | >10 to 20 | 150 |
| | >5 to 10 | 50 |
| | Up to 5 | 25 |
| 44 (25%) | >20 to 40 | 125 |
| | >10 to 20 | 75 |
| | >5 to 10 | 25 |
| | Up to 5 | 25 |

*High Density Polyethylene

**Low Density Polyethylene

Buffer zone reductions of 10% each are allowed for applications where flat fume fumigation is used, when high barrier films are used, and when the soil has an organic matter content of ≥ 3 . The buffer zone for applications utilizing all 3 credits can be reduced by 30%. However, the minimum buffer zone is always 25 ft regardless of credits.

Application sites must be limited to ≤ 40 acres/day, and the buffer zone of the field to be treated cannot overlap the buffer zone of another field treated within the last 48 hours.

3. The certified applicator is responsible for establishing the buffer zone and ensuring that workers or bystanders do not enter the buffer zone for 48 hours following the end of the application. An exception will be allowed for transit through the buffer zone, e.g. < 15 minutes for roads and vehicle passage ways where transit is unavoidable.
4. Currently, all certified applicators are required to maintain records related to their use of restricted use pesticides. In addition, for iodomethane, certified applicators must maintain records that demonstrate the method of buffer zone calculations, buffer zone size, how applications met sensitive site requirements, and how occupied structures were handled.
5. Use within $\frac{1}{4}$ mile of any occupied sensitive site such as a school, day care facility, nursing home, hospital, prison, or playground is prohibited.
6. Certified applicators must be on site and within the line of sight of the field during application.
7. The registrant is instituting a training/stewardship program for certified applicators. Product labels require that the certified applicator must complete the registrant's training program and be certified by Arysta before using the iodomethane product. Sale of iodomethane will be limited to certified applicators that have completed the registrant's training and certification program.
8. The entry restricted period is five days.
9. Tarp monitors, shovelers, tractor drivers and co-pilots must wear a respirator which meets standards specified by the Occupational Safety and Health Standards Agency

(OSHA). In addition, respirator users must be trained using a program that conforms to OSHA requirements and must be examined by a qualified medical practitioner to ensure physical ability to safely wear a respirator. Tractor drivers and co-pilots will have the option of using a ducted fan/blower in lieu of the respirator.

10. Non-handler entry is prohibited while tarps are being removed.

DATA GAPS

There are no data gaps for iodomethane. The Agency has identified data which, if supplied, could help to further refine the risks and possibly result in reduced buffer zones.

PUBLIC INTEREST FINDING

The registration of a new pesticide ingredient is presumed to be in the public interest if: 1) the pesticide is a replacement for another pesticide that is of concern to the Agency; 2) the pesticide has a use for which a Section 18 emergency exemption has been granted because of the lack of a suitable alternative; or 3) the pesticide is to be used to control a pest of public health significance. If none of these criteria apply, then it must be shown that: 1) there is a need for the new pesticide that is not being met by currently registered pesticides; 2) the new pesticide is less risky than currently registered pesticides; or 3) the benefits from the new pesticide are greater than those from currently registered pesticides or non-chemical control measures. The Agency believes that registering iodomethane is in the public interest based on the designation of iodomethane as a methyl bromide (MeBr) replacement, agricultural need, and the likely benefits.

Methyl bromide is an odorless, colorless gas used as an agricultural soil and structural fumigant to control a wide variety of pests. However, MeBr has been implicated in the depletion of the stratospheric ozone layer allowing increased amounts of radiation to reach the earth's surface, with potential impact to not only human health and the environment, but to agricultural crops as well. Consequently, the industrialized nations agreed to phase out the use of MeBr, except for certain allowable exemptions. In the United States, the phaseout was finalized on January 1, 2005, except for specific exemptions. Specific exemptions were allowed because alternatives to some MeBr uses that are technically and economically feasible, as well as acceptable from a public health viewpoint, have not yet been identified.

UVB radiation (280 to 320 nanometer range) has been implicated in DNA damage and increased incidence of melanoma type cancers. UVB has also been linked to changes in plant physiology; marine ecosystems (particularly phytoplankton populations); buildup of greenhouse gasses; and weakening of some materials. Increased amounts of UVB are expected to reach the earth's surface if atmospheric ozone levels decrease. Since the sun's output of UVB is constant, less ozone will result in less protection from this potential harmful radiation. Research demonstrates that surface UVB levels can double during the annual ozone hole.

In addition to being implicated in malignant melanoma and non-melanoma skin cancers, UVB has also been linked to cataracts in humans. Limited exposure to sunlight is important in

reducing exposure to UVB and its impact on health; however, a reduction in atmospheric ozone levels will increase the amount of UVB and consequent health risks.

Solar UVB radiation affects the early developmental stages of fish, shrimp, crab, amphibians, and other animals, often causing exposed animals to exhibit decreased reproductive capacity and impaired larval development. UVB may have an even more fundamental deleterious affect on marine ecosystems by reducing survival rates in phytoplankton. Phytoplankton forms the foundation of aquatic food webs and is limited to the upper layer of the water column in which there is sufficient sunlight to support their growth.

Although plants have a limited ability to adapt to increased levels of UVB, the radiation can change how nutrients are distributed within the plant and the timing of developmental stages. The potential impact of such UVB-mediated changes on plant ecosystem competition, plant disease, and biogeochemical cycles is largely unknown.

Increases in solar UV radiation could affect terrestrial and aquatic biogeochemical cycles, thus altering both sources and sinks of greenhouse and chemically important trace gases e.g., carbon dioxide (CO₂), carbon monoxide (CO), carbonyl sulfide (COS) and possibly other gases, including ozone. These potential changes would contribute to biosphere-atmosphere feedbacks that attenuate or reinforce the atmospheric buildup of these gases.

UVB radiation can also weaken materials such as synthetic polymers, naturally occurring biopolymers, and other materials of commercial interest. Today's materials are somewhat protected from UVB by special additives. However, any increase in solar UVB levels will accelerate their breakdown, thereby limiting the length of time for which they are useful outdoors.

The Agency recognizes the importance of the pesticidal activity of a material like MeBr to the agricultural community, and is committed to assist the agricultural sector with the transition to alternative pest control tools. Iodomethane was proposed for use as an alternative pre-plant fumigant for MeBr in field grown ornamentals, nursery grown strawberries, stone fruits, tree nuts, and conifer trees, and field grown peppers, strawberries, stone fruits, tree nuts, tomatoes, and turf. Iodomethane is short-lived in the lower atmosphere and unlikely to reach the upper atmosphere to deplete the ozone layer.
