SECTION 1.0 INTRODUCTION

The U.S. Environmental Protection Agency, Region I, New England (EPA) headquartered in Boston, Massachusetts contracted with Metcalf & Eddy, Inc. (M&E), of Wakefield, Massachusetts under EPA's Response Action Contract (RAC) to provide Remedial Investigation/Feasibility Study (RI/FS) services for Operable Unit 4 (OU-4) of the Iron Horse Park Superfund Site in North Billerica, Massachusetts (the Site). This Data Evaluation Report will help to form the basis for a focused ecological risk assessment that will be performed as an addendum to the baseline ecological risk assessment (BERA) conducted for Operable Unit 3 (OU-3) (M&E, 1997).

1.1 Site Background

The Iron Horse Park Superfund Site occupies approximately 553 acres in North Billerica, Massachusetts, near the Tewksbury town line, approximately 20 miles northwest of Boston (Figure 1-1). The Site is bounded on the north by the B&M railroad tracks, on the west by High Street and an auto salvage yard, on the east by Gray Street, and on the south by a wetland, Pond Street, and the Middlesex Canal (Figure 1-2). The Middlesex Canal flows through the Site to the east, where it joins Content Brook at the southeastern edge of the Shaffer Landfill. It then flows to the Shawsheen River and ultimately to the Merrimack River to the north. There are abundant wetlands and forested areas at the Site. Approximately 20% of the Site is forested while 17% is wetland habitat. In addition, several large wetland complexes border the Site which increases the total acreage of the wetlands at the Site to 266 acres.

The Site is divided into four operable units. OU-1 is the Boston & Maine (B&M) Wastewater Lagoons, OU-2 is the Shaffer Landfill, and OU-3 is the remainder of the Site. OU-3 includes an active industrial complex (the Iron Horse Industrial Park), a railyard, numerous manufacturing operations, open storage facilities, landfills, and lagoons. Investigational activities, including a BERA, were completed for OU-3 in 1997. M&E is charged with conducting additional investigative activities and a focused ecological risk assessment and feasibility study for the Site (OU-4) in order to support selection of a remedy to control ecological risks to the environment.

The investigational activities included supplemental sampling of surface water, sediment, and fish to better characterize ecological risks identified during the BERA conducted for OU-3 (M&E, 1997). The objective of the focused ecological risk assessment for OU-4 is to determine the risk of adverse effects of contaminants in sediment, surface water, and biota on ecological receptors, either through direct exposure to contaminants in sediment and surface water or through indirect exposure through the food web. Previous investigations established that concentrations of some contaminants exceed screening-level benchmarks in surface water and sediment. A benthic community study indicated that there was no discernible impact at about 20 site locations relative to five reference locations. Screening-level food web modeling indicated that there were potential effects on heron through fish consumption based on modeled (not measured) fish tissue contaminant concentrations. Therefore, the sampling and analysis program for the work described herein was designed to measure toxicity of sediment and surface water on aquatic organisms and to refine the food web model for heron using fish tissue analysis and updated toxicity reference values from the literature.

The RI/FS Addendum (OU-4) will supplement the RI (M&E, 1997) and FS (M&E, 2004a) for OU-3.

1.2 Site History

The Site was first purchased by the B&M Railroad (now known as B&M Corporation) in 1911. Since 1911, a variety of industrial disposal practices have resulted in the creation of numerous lagoons, landfills, and open storage areas. The B&M Railroad began operations at the Site in 1913, including the operation of an oil and sludge recycling area beginning sometime prior to 1938. The B&M Railroad has operated the Site's sewage collection system since 1924. The system includes subsurface sewer lines, a dismantled pump house, two unlined filter lagoons, and one overflow lagoon (these wastewater lagoons are OU-1). In addition to septic wastes, the lagoons also received industrial/hazardous wastes such as solvents, waste oils, and other chemicals from various floor and yard drains found throughout the industrial park. Sludge from the bottom of these lagoons was periodically dredged during the past 60 years of operation and deposited in piles adjacent to the lagoons.

In 1944, the B&M Railroad sold land in the western portion of the Site to Johns-Manville Products Corporation, which at that time began to manufacture structural insulating board that contained asbestos. Three unlined lagoons were built to dispose of the resulting asbestos sludge waste. The B&M Railroad also leased land in the eastern portion of the Site to Johns-Manville to be used as a landfill for asbestos sludge and other asbestos mill wastes generated by their manufacturing operations. EPA capped this landfill in 1984.

In 1961, the Johns-Manville Products Corporation sold the western portion of its land to the General Latex and Chemical Corporation, which manufactured acrylic and vinyl acetate polymers and copolymers used in fabrics, paper, and insulation. The liquid filtrate from the latex and polymerization wastes was discharged to the ground through sand filters. This practice was discontinued in May 1982, when General Latex was connected to the Billerica sewer system.

In 1966, the B&M Corporation sold 106 acres of land north of the Middlesex Canal and east of Pond Street to Phillip Shaffer. This land later became the Shaffer Landfill and is currently OU-2 of the Site. This landfill received commercial and residential waste materials from private clients, wastewater treatment sludge from the town of Billerica, and domestic waste from Billerica residents. The landfill stopped receiving waste in April 1986. The Potentially Responsible Parties (PRPs) completed construction of the remedy for the landfill in 2003.

According to 1969 aerial photographs, the B&M Corporation was using a parcel of land located east of the railyard on the south side of the Middlesex Canal as a borrow pit for sand and gravel. This area was leased by B&M Corporation to Reclamation Services, Inc. (RSI) for use as a landfill to dispose of municipal and light industrial waste. In 1976, the B&M Corporation sold approximately 150 acres of primarily developed land to the Massachusetts Bay Transportation Authority (MBTA), which has since used the land to operate passenger rail service. The B&M Corporation now leases much of this land from the MBTA.

M&E finalized the RI for OU-3 in 1997. RI sampling data collected between June 1993 to August

1995 for groundwater, surface soil, subsurface soil, surface water, and sediment from nine potential source areas within the Site (the B&M Railroad Landfill, B&M Locomotive Shop Disposal Areas, the Reclamation Services Inc. [RSI] Landfill, the Old B&M Oil/Sludge Recycling Area, the Contaminated Soils Area, the Asbestos Landfill, the Asbestos Lagoons, and Site-Wide Surface Water and Sediment Contamination) indicates the presence of contaminants. A BERA was also conducted as part of the RI for OU-3 (M&E, 1997). The following sections briefly describe contamination previously detected at the areas of concern and in site-wide surface water and sediment, and provide a summary of the results of the BERA conducted for OU-3.

B&M Railroad Landfill. The B&M Railroad landfill is approximately 14 acres in size and is located in a wetland area, north of the Middlesex Canal and east of the railyard. The wetland was filled in by the B&M Railroad and used to dispose of various kinds of debris. Similar types of organic compounds including volatile organic compounds (VOCs), polynuclear aromatic hydrocarbons (PAHs), phthalates, petroleum hydrocarbons, pesticides, and polychlorinated biphenyls (PCBs) were detected in surface and subsurface soils, with the highest concentrations occurring in subsurface soils. These contaminants were considerably less prevalent in groundwater.

RSI Landfill. The 6-acre RSI Landfill, located east of the B&M railyard near the Johns-Manville Asbestos Landfill, is bounded on the south by an unnamed brook and on the east by a wetland, which is drained by the Middlesex Canal. Waste and fill present in the west-central portion of the landfill include organic compounds and metals, detected in subsurface soils, and pesticides, PCBs, and phthalates, found in subsurface and surface soils. Aromatic VOCs, pesticides, and PCBs were detected in groundwater at low concentrations.

B&M Locomotive Shop Disposal Areas. The B&M Locomotive Shop Disposal Areas consist of two disposal areas (A and B) separated by a manmade channel that flows into an unnamed brook. Metals and organic compounds including pesticides, PAHs, and petroleum hydrocarbons were detected in surface and subsurface soils in both areas. An isolated occurrence of PCBs was also noted at one subsurface soil location. A few organic compounds (including one VOC, a few pesticides, and one PCB Aroclor) and metals were detected in groundwater in the downgradient and vicinity wells.

Old B&M Oil/Sludge Recycling Area. The 6-acre, Old B&M Oil/Sludge Recycling Area was established sometime prior to 1938 for the purpose of recycling oil. Contaminants detected in surface and subsurface soils consist primarily of PAHs, long-chain alkanes, and petroleum hydrocarbons. Numerous pesticides and PCBs were detected in the northern area, and metals were measured in both areas. Although aromatic VOCs, PAHs, and petroleum hydrocarbons were generally not present in groundwater, chlorinated VOCs and metals were detected. Metals, which were detected primarily in shallow overburden groundwater, included arsenic, chromium, cobalt, lead, mercury, nickel, and zinc. Petroleum hydrocarbons were measured in one well and several inches of floating product were observed in one piezometer in the southern oil/sludge area.

Contaminated Soils Area. The Contaminated Soils Area is located in the center of the Site and is approximately 50 acres in size. Contaminated soil was first identified as a problem in this area after a random soil boring program conducted across the Site indicated elevated levels of lead (310 to 76,600 parts per million [ppm]) at nine out of forty locations. Organic compounds, including PAHs, petroleum

hydrocarbons, and pesticides, were measured in surface soils in localized areas. Lead and manganese were the metals that were detected most often and in the highest concentrations.

Asbestos Landfill. The Site has historically been identified with asbestos contamination due to asbestos landfilling operations conducted by Johns-Manville over a 32-year period. Although EPA capped the Asbestos Landfill in 1984, asbestos materials have been found outside the limits of the cap. However, the results of the off-site soil sampling indicated that, with one exception, there were no detectable levels of asbestos in residential areas. No additional analytical data were collected for this area as part of the RI.

Asbestos Lagoons. In addition to the Asbestos Landfill, there are three unlined asbestos lagoons on Johns-Manville property. Groundwater samples collected from beneath the lagoons contained VOCs (primarily aromatic and chlorinated VOCs), PAHs, PCBs, and pesticides. Chlorinated VOCs and metals (arsenic, cobalt, lead, and zinc) were detected in the shallow overburden, deep overburden, and bedrock flow zones.

Site-Wide Surface Water and Sediment Contamination. Two rounds of surface water and sediment sampling conducted in June and September of 1993 revealed aromatic and chlorinated VOCs at multiple surface water locations. In general, PAHs, pesticides, and metals were detected more often and in higher concentrations in the data from the June sampling round compared to data collected in September. In the vicinity of Shaffer Landfill, specific conductance and metals concentrations were higher than in other areas of the site. Similar to surface water, the frequency of detection and the concentrations of contaminants in sediment, including aromatic and chlorinated VOCs, PAHs, pesticides, and PCBs, were generally greater in June than September. Metals were detected at similar concentrations during both sediment sampling rounds.

Baseline Ecological Risk Assessment Summary. The BERA for the Site included an evaluation of the potential adverse effects of site contaminants of potential concern (COPCs) to receptor populations in both terrestrial and aquatic habitats. Areas of concern for terrestrial habitats are the seven areas described above. Aquatic habitats were separated into the West Middlesex Canal Group, Wetland 2 Group, East Middlesex Canal Group, Richardson Pond Group, and Content Brook Wetland Group as shown on Figure 1-2.

Adverse effects to soil invertebrates and dietary exposures of semivolatile organic compounds (SVOCs), pesticides, and metals to short-tailed shrews from the ingestion of earthworms, surface soil, and surface water at the B&M Railroad Landfill, RSI Landfill, and B&M Locomotive Shop Disposal Areas (Areas A and B) were evaluated. The results of the earthworm and short-tailed shrew analyses indicated the potential for reductions in both soil invertebrate and small mammal populations at the B&M Railroad Landfill and B&M Locomotive Shop Disposal Areas (Areas A and B). In general, metals and SVOCs (mostly PAHs) are the two contaminant groups of concern. The proposed remedies (source control via capping and/or excavation) for these areas are expected to eliminate the exposure pathways for terrestrial receptors.

The evaluation of ecological risk in aquatic habitats identified minimal risks from surface water in the

Middlesex Canal. The results of the evaluation of potential risks to benthic receptors due to exposure to sediment COPCs in the Middlesex Canal indicate potential risks in West Middlesex Canal from exposure to SVOCs and also from exposure to copper, lead, PCBs, and 4,4'-DDD on a limited spatial scale. The evaluation also indicated the potential for adverse effects on aquatic populations as a result of the observed concentrations of metals in surface water in the Wetland 2 Group (barium, iron, and lead), Richardson Pond Group (barium, iron, and lead), and Content Brook Wetland Group (barium, aluminum, arsenic, iron, manganese, and silver). Results of the sediment analysis for benthic receptors indicated potential adverse effects on benthic invertebrate communities could occur as a result of the observed concentrations of PAHs and metals in sediments in the Wetland 2 Group, Richardson Pond Group, and Content Brook Wetland Group. Although the sediment contaminant concentrations indicated the potential for adverse effects, this result was not supported by the qualitative benthic community data. A potential for adverse effects on migratory bird populations was identified in the Wetland 2 Group, Richardson Pond Group, and the Content Brook Wetland Group from exposures to metals (particularly mercury and zinc) and SVOCs (particularly dibenz[a,h]anthracene).

Based on the results of the BERA, the primary COPCs identified include 4,4'-DDD in sediment, PAHs in sediment, PCBs in sediment, and target metals (aluminum [Al], arsenic [As], barium [Ba], manganese [Mn], silver [Ag], chromium [Cr], cobalt [Co], copper [Cu], lead [Pb], vanadium [V], and zinc [Zn]) in surface water and sediment. In addition, there was potential risk associated with dietary exposures of great blue heron to target metals and PAHs through the ingestion of fish.

1.3 Conceptual Site Model

The conceptual site model (CSM) summarizes the release of contaminants from industrial and urban sources, which have been transported through groundwater discharge, surface drainage, and sediment transport (secondary sources) to surface water and sediment within various area of the Site. The complete ecological exposure pathways are also summarized in the CSM (Figure 1-3).

As described in Section 1.1, groundwater, surface water, sediments, and soil contamination were studied in the RI/FS for OU-3. Groundwater in both the overburden and bedrock aquifers generally enters the Site from the southwest and flows to the northwest. Similarly, surface water flows onto the Site from the south and flows to the northwest, where it converges with B&M Pond and associated wetlands. Based on seepage meter, staff gauge, and mini-piezometer results summarized in the OU-3 RI/FS (M&E, 1997 and M&E, 2004a), the potential for groundwater to discharge to surface water was evident throughout most of the Site.

Groundwater studies conducted as part of the OU-3 RI/FS included groundwater modeling, which utilized site-specific information such as boring logs, slug tests, water levels from monitoring wells and staff gauges, and stream seepage tests to simulate groundwater migration used to estimate relative times to achieve remedial action objectives (RAOs) for groundwater cleanup. The modeling indicated that the time to reach RAOs was greater than the EPA default period of 30 years. As a result, EPA decided to address potential groundwater cleanup by initially performing source control measures, then monitoring groundwater and evaluating trends in contaminant concentrations that result from those actions.

Contaminated sediments and surface water at the Site are likely the result of contaminated groundwater discharge and runoff containing contaminated soils. Based on the transport pathways described and the results of the baseline ecological risk assessment conducted for OU-3 (see Section 1.2), the primary ecological receptors for potential exposure to contaminated media at the Site include organisms such as benthic invertebrates and aquatic receptors directly exposed to contaminants in sediment and surface water, and migratory birds that feed primarily on fish that may be impacted by site-related contamination. The aquatic and semiaquatic receptors include organisms such as invertebrates in the surface water (zooplankton community), warmwater fish, predatory birds, and benthic invertebrates exposed to sediments affected by COPCs. Based on the OU-3 BERA results, the indicator species and indicator communities identified at the Site selected for further evaluation included aquatic receptors (zooplankton and fish), benthic invertebrates, and predatory birds, represented by the great blue heron.

Each of these indicator species or indicator communities may be exposed to substantial levels of contaminants through direct contact with and consumption of contaminated abiotic media or through the consumption of prey items that carry contaminant body burdens. The CSM shows the exposure pathways by which these species may be exposed to COPCs (Figure 1-3). This model allows evaluation of direct and indirect (food-chain) impacts on major components of the aquatic and semi-aquatic food chains at the Site.

1.4 Problem Definition/Present Study

To date, investigational work performed at the Site has identified the potential for ecological risks associated with the presence of COPCs in surface water, sediment, and biota. This work assignment focuses on supporting the selection of a remedy by collecting environmental data to fill data gaps and determine the actual risk of adverse effects to ecological receptors. The focused ecological risk assessment will be used to select an approach for control of ecological risks at the Site that results in a well-supported Record of Decision for the Site.

Specifically, the investigation was designed to address:

- Risks to aquatic receptors directly exposed to target metals in surface water in the Middlesex Canal (downgradient of the Johns-Manville outfall), Richardson Pond, B&M Pond, and Content Brook;
- Risks to benthic invertebrates directly exposed to 4,4'-DDD, PCBs, PAHs, and target metals in sediment within the on-site wetlands and ponds; and
- Risks to predatory birds (e.g., heron) indirectly exposed to PAHs and target metals in biota within the Middlesex Canal (downgradient of the Johns-Manville outfall), Richardson Pond, B&M Pond, and Content Brook.

To address these specific risk issues, supplementary surface water, sediment, and fish tissue samples were collected for the focused risk assessment. Samples collected and analyses conducted are summarized in Table 1-1. Surface water samples were collected from one reference area (Round Pond) and four surface water areas on-site including the Middlesex Canal, Richardson Pond, B&M Pond, and

Content Brook. These samples will be used to evaluate toxicity to aquatic receptors from exposure to metals in surface water. Fish tissue samples were also collected at these five open water locations (four on-site and one reference) to model dietary exposure of heron based on site-specific fish tissue concentrations of PAHs and target metals.

Sediment samples were collected to further evaluate toxicity to benthic invertebrates from exposure to 4,4'-DDD, PCBs, PAHs, and metals in sediment within the on-site wetlands and ponds. Sediment samples were collected in a phased approach. Based on historic data and a site reconnaissance, twenty on-site sampling locations and three reference locations were selected for screening-level analysis for target metals, PAHs, PCBs, and Microtox® toxicity, using standard field-screening methods, which are further described in Section 3. Based on the field screening results, a subset of four on-site sediment sampling locations were selected to represent the sediments with highest potential toxicity. The least toxic/contaminated location among the three potential reference locations was selected for analysis as the representative reference location. These five sediment samples, including four non-reference and one reference location, were evaluated using laboratory sediment toxicity testing and analytical methods. These data will be used to evaluate the potential toxicity of site-related contaminants on benthic organisms from locations representing the highest contaminant levels based on historic data and screening results.

The data from the sediment, surface water, and fish sampling described above are evaluated in this report in preparation for use in the focused ecological risk assessment.

SECTION 2.0 FIELD OPERATIONS

This section summarizes the field activities conducted by M&E at the Site in September and October 2004. The design details of the field program are described in the *Sampling and Analysis Plan (Field Sampling Plan and Quality Assurance Project Plan) for Remedial Investigation/Feasibility Study Addendum (OU-4) - Revision 00, Iron Horse Park Superfund Site, North Billerica, Massachusetts (SAP) (M&E, 2004b)*.

2.1 Field Activities

Field activities were conducted at the Site from September 13, 2004 to October 1, 2004 in accordance with the SAP (M&E, 2004b). EPA's primary objective for the sampling activities was to provide sufficient data to support the focused ecological risk assessment.

To achieve EPA's objective, M&E collected 23 sediment samples, 5 triplicate surface water samples, and 124 fish, which were later composited into 25 fish samples. Non-reference sediment sampling locations selected for field screening are shown on Figure 2-1. Non-reference surface water and fish sampling locations are shown on Figure 2-2, along with non-reference sediment samples selected for full characterization based on the screening-level analyses. As identified in Figure 2-2, non-reference (or site) sediment sampling locations SED-01, SED-05, SED-11, and SED-18 were selected for full characterization. Figure 2-3 shows reference sediment (screening locations), surface water, and fish sampling locations. Reference sediment sampling location SED-22 was selected for full characterization. Photographs of sampling locations are provided in Appendix A.

2.1.1 Sampling Locations

Sampling locations were selected during a site reconnaissance conducted on July 8, 2004 and attended by M&E personnel, the EPA RPM and EPA ecological risk assessor, and the Massachusetts Department of Environmental Protection (MADEP) project manager. Sediment sampling locations were selected based on their positions in relation to historical sampling locations which had shown elevated levels of contamination and visual observations made during the site reconnaissance. In most cases, the staked location from historical sampling was located and samples were collected within a few feet of the previously sampled location. If a previous sampling location was not located or if sampling was to occur in a new location, the sediment sampling locations were selected based on where sediment deposition was likely to have occurred. Sediment sampling locations are shown on Figures 2-1 and 2-3.

Fish and surface water sampling locations were selected based on habitats that could support fish. Fish and surface water sampling locations are shown on Figures 2-2 and 2-3.

Sediment Sampling Locations

The locations and rationale for sediment sample selection are provided below. Further details regarding the rationale for the selection of sediment sampling locations from historical data are provided in Table 2-1. Overall, locations were selected to provide a representative sampling of the wetland areas across the Site.

Sediment samples SED-01, SED-02, SED-03, and SED-04 were collected from the Content Brook Area. All of these samples were collected within the vicinity of historical sampling locations which had reported exceedances of preliminary remediation goals (PRGs) as identified in the OU-3 FS (M&E, 2004a).

Sediment samples SED-05, SED-06, and SED-07 were collected on the shores of B&M Pond. Two of these three locations (SED-05 and SED-06) were collected near locations with historical PRG exceedances. The third sample, SED-07, was collected in the northwest corner of B&M Pond. This location was selected to provide better spatial coverage of the pond.

Sediment sample SED-08 was collected within the wetland just off the East Middlesex Canal, south of the B&M Railroad Landfill. This location is in the vicinity of a previously collected sample which had historical PRG exceedances.

Sediment samples SED-09, SED-10, SED-11, and SED-12 were collected within the West Middlesex Canal. Samples from the West Middlesex Canal have historically shown elevated concentrations of PAHs. In addition, SED-11, located just downstream of the Johns-Manville outfall, was sampled in the vicinity of the location with the reported highest historical PCB concentration.

Sediment samples SED-13, SED-14, SED-15, and SED-16 were collected within Richardson Pond and the surrounding wetlands. One sampling location (SED-13) was located within an area that had historically reported PRG exceedances. This wetland area was considered a likely habitat for heron, a receptor to be included in the focused ecological risk assessment.

Sediment samples SED-17, SED-18, SED-19, and SED-20 were collected within the Unnamed Brook. These samples were all collected within the vicinity of previous sampling locations for which exceedances of PRGs were reported.

Sediment samples SED-21, SED-22, and SED-23 were collected within Round Pond. These samples were collected to serve as reference locations.

A survey of all sediment sampling locations was conducted by M&E using a hand-held GPS unit. The survey was conducted in accordance with the following standards: Horizontal Controls are geographic coordinates WGS 84 (World Geodetic System of 1984). Vertical datum was not recorded. GPS coordinates for sediment sampling locations are provided in Appendix B.

Surface Water Sampling Locations

Surface water samples were collected in triplicate at five locations corresponding to where fish sampling was to occur, including Richardson Pond (SW-RP samples), Content Brook (SW-CB samples), West Middlesex Canal (SW-MC samples), B&M Pond (SW-BM samples), and Round Pond (SW-RF reference samples). Surface water sample nomenclature includes the location prefix (e.g. SW-CB) and a suffix (i.e. -01, -02, or -03) indicating triplicate sample identifications.

Fish Sampling Locations

Fish samples were collected from four on-site surface water bodies (B&M Pond, Richardson Pond, Middlesex Canal down gradient of the Johns-Manville outfall, and Content Brook) and the reference water body (Round Pond). Initially, the fish collected were assigned a subsample ID. This was done because most fish collected were not of sufficient weight to constitute a sample, and therefore, were expected to be composited. Once composited, there were 25 fish samples for analysis. Once composited, sample nomenclature included a location prefix (e.g., BM for B&M Pond), followed by a species abbreviation (e.g. BB for brown bullhead and GS for golden shiner), and then a sequential sample number. For example, fish tissue sample MC-AE-1 was a composite sample of American eel collected from the West Middlesex Canal.

2.1.2 Sediment Sampling

Sediment samples were collected from September 13, 2004 through September 20, 2004. All twenty-three sediment samples were collected with an Eckman dredge, which generally captures the first six inches of sediment below the sediment-water interface. Collected sediment was placed in one or more stainless steel bowls and photoionization detector (PID) readings were taken and recorded (Appendix C). Sediment was then homogenized with a stainless steel spoon or trowel, and grain size, Munsell color, and sample descriptions were recorded on field sampling sheets. Depth to the river bottom was also measured and recorded. Sediment was placed into sampling containers and immediately placed in a cooler with ice (with the exception of sample aliquots for grain size analyses). Samples were later recorded onto chain-of-custody (CoC) forms and submitted to laboratories to be held for possible analysis.

All sampling equipment was decontaminated between each sample location according to M&E standard operating procedures (SOPs) in accordance with M&E's SAP (M&E, 2004b). Sediment sampling field data sheets are provided in Appendix C.

Sediment samples were collected for the initial screening of toxicity with Microtox®, PAHs and PCBs with immunoassay test kits, and target metals except aluminum by X-Ray Fluorescence Spectroscopy (XRF). In addition, sediment was collected for possible full characterization, including analyses for toxicity, 4,4'-DDD/PCBs, PAHs, target metals, total organic carbon (TOC), and grain size in accordance with the SAP (M&E, 2004b). Samples were preserved with ice. Additional sample volume was collected from sediment location SED-05 for field duplicate analyses. The sample location identification used for the field duplicate was SED-25. At locations SED-21, SED-22, and SED-23, additional sample volume was collected for Matrix Spike/Matrix Spike Duplicate (MS/MSD) analyses

for PAHs, 4,4'-DDD/PCBs, target metals, and TOC. Equipment blanks were also collected and submitted for analyses. A temperature blank was included with each cooler prior to sample shipment. CoC documentation for each sample shipment is included in Appendix D. Upon arrival at the laboratories, sediment samples were frozen to suspend the holding times while awaiting a decision concerning those samples to undergo full characterization.

2.1.3 Surface Water Sampling

Surface water samples were collected in triplicate from five locations within various water bodies located in and around the Site from September 21, 2004 through September 24, 2004. Surface water sampling was conducted prior to electroshocking for fish to minimize sediment disturbances caused by the electroshocker, which could potentially lead to elevated turbidity levels in the surface water samples.

Surface water samples were collected using a teflon-coated dipper to transfer sample aliquots to sample containers. For the dissolved target metals sample aliquot, surface water was placed into an interim bottle from which volume was later pumped through a 0.45 µm filter and transferred to another bottle to be submitted to the laboratory. All samples were preserved according to analytical methodologies, placed in a cooler with ice, documented onto a CoC form, and submitted for laboratory analyses.

At each sampling location, the depth of the water column was measured and velocity of the current was visually estimated and recorded. In addition, water quality and field parameters (pH, dissolved oxygen, specific conductivity, oxidation reduction potential [ORP], temperature, and turbidity) were measured and recorded.

Non-dedicated sampling equipment (i.e., the dipper) was decontaminated between each surface water sampling location according to SOPs in the SAP (M&E, 2004b). Surface water sampling field data sheets are provided in Appendix C.

All surface water samples were collected for analysis of toxicity to daphnia and minnow, target metals (total and dissolved), and alkalinity in accordance with the SAP (M&E, 2004b). Samples collected for target metals analysis were preserved with nitric acid (HNO₃). Alkalinity and toxicity testing samples were not preserved. Additional sample volume was collected from location SW-MC-01 (the first of the triplicate samples collected in the West Middlesex Canal) for field duplicate analyses for target metals and alkalinity. The sample location identification used for the field duplicate was SW-MC-21. At location SW-RF-01, additional sample volume was collected for MS/MSD analyses for target metals and alkalinity. Equipment blanks (for total and dissolved target metals) were collected and submitted for analysis. A temperature blank was included with each sample shipment. CoC documentation for each sample shipment is included in Appendix D.

2.1.4 Fish Sampling

Fish samples were collected from four on-site surface water bodies (B&M Pond, Richardson Pond, Middlesex Canal down gradient of the Johns-Manville outfall, and Content Brook) and the reference water body (Round Pond) consistent with the SAP (M&E, 2004b) procedures. Coinciding with surface water sampling, the initial fish sampling event occurred during the week of September 21, 2004 through September 24, 2004. M&E in consultation with EPA, conducted an additional three days of fish sampling from September 29, 2004 through October 1, 2004. Additional fish sampling was necessary to obtain sufficient sample mass for brown bullhead (*Ameiurus nebulosus*) from Content Brook and Round Pond.

At each location, five 50-gram samples were targeted which consisted of either a single fish or a composite of multiple fish of the same species. After all samples were collected, EPA in consultation with M&E, decided which specific fish from each area would be composited by the laboratory for analysis. Each composited fish sample was analyzed on a whole fish basis for total lipids, target metals, and PAHs.

Prior to fish sampling, a Scientific Collection Permit was filed with the Massachusetts Department of Fisheries and Wildlife (Appendix E). During the week of September 21, 2004 through the 24, 2004, fish were collected at all locations using a direct-current (DC) powered backpack electroshocker. Sampling was conducted by wading in a downstream to upstream fashion within Middlesex Canal and Content Brook. At locations where water levels were too deep or the substrate too soft to allow wading, the field crew used either a canoe or a small inflatable zodiac boat. In all pond locations, including Richardson Pond, B&M Pond, and Round Pond, electrofishing was conducted in anticipated fish habitat (i.e., submergent and emergent vegetation) in water depths up to four feet.

During the week of September 29, 2004 through October 1, 2004, fish were collected using a combination of sampling gear including hoop nets, trot lines, gill nets, and angling. Fish within Round Pond and Content Brook were collected using baited hoop nets and trot lines which were soaked overnight and collected the following morning. Gill nets and angling were also used to supplement fish collection within Round Pond. Gill nets, consisting of variable mesh sizes (2.0-inch, 2.5-inch, 3.0-inch and 3.5-inch), were soaked for two hour sets. At all locations, an on-shore observer was present during fish sampling events.

All collected fish were placed into holding bins which consisted of a tank with sufficient water to maintain proper temperature and oxygen levels to minimize stress. All fish collected were kept alive until final decisions were made regarding which individuals were to be retained for fish tissue analysis. All fish selected for the fish tissue analysis were euthanized, enumerated, identified to species, and measured for length and weight. Scales or fin samples were also removed for potential age analysis. Whole body fish samples were then packed in dry ice and shipped to the laboratory for processing and analysis. All fish sampling field data sheets are provided in Appendix C.

2.2 Field Observations

Field observations made during the sampling of sediment, surface water, and fish are detailed below.

2.2.1 Sediment Observations

Field observations made during sediment sampling are provided herein, by area. A summary of sediment sample descriptions is provided in Table 2-2. Field sampling sheets are included in Appendix C.

Content Brook Area

Sediment samples collected within the Content Brook Area were generally dark brown or dark gray in color and consisted of silt and fine or very fine sand. The one exception was that only silt with some organic material was noted in sediment sample SED-02, which was collected within a phragmites wetland at the foot of Shaffer Landfill.

Sediment sample SED-01 was collected in a very shallow stream (water depth less than 2 inches). This sediment sample was stained with an orange color and appeared to have a sheen. A hydrocarbon odor was noted for this sample, as well as sediment sample SED-02. A sulfide odor was noted for sediment sample SED-04.

B&M Pond

Sediment samples collected from B&M Pond (SED-05, SED-06, and SED-07) and in the vicinity (SED-08) were characterized as black or very dark grayish brown silt and fine or very fine sandy sediment with some organic material, including roots, leaves, and twigs. A sheen was observed on the surface water when sediment samples SED-05, SED-07, and SED-08 were collected.

West Middlesex Canal

Sediment samples collected within the West Middlesex Canal consisted of silt and various classes of sand and were very dark grayish brown or black in color. The canals are tree-lined and all samples contained twigs. A sheen on the water surface was noted when samples SED-09, SED-10, and SED-12 were collected.

Richardson Pond

Sediment samples collected within Richardson Pond were characterized as very dark gray or brown silt, with little or some fine sand and/or coarse sand. All samples contained some amount of organic matter, consisting of wetland vegetation and phragmites roots. The surface water in Richardson Pond, where the sediment samples were collected, was stained with limited visibility. Surface sheens were observed at SED-13 and SED-15.

Unnamed Brook

Sediment samples collected from the Unnamed Brook (SED-17, SED-18, SED-19, and SED-20) contained silt and various sand classes that were very dark gray or black in color. A sheen on the water surface was noted at all locations.

Reference Area - Round Pond

Samples collected at Round Pond were very dark brown or black in color and consisted of silt and fine

or very fine sand. A high organic fraction (i.e., leaves and roots) was noted for SED-21 and SED-22; only some twigs were noted for sample SED-23. Stained water was noted above all sample locations and a sulfide odor was noted for SED-21.

2.2.2 Surface Water and Fish Observations

Observations made during surface water and fish sampling are discussed together within this section, as these samples were collected concurrently. Observations are discussed by surface water body. Fish data collected, such as weight and length, are considered results, and thus, are discussed in Section 6.

At all surface water bodies, water quality parameters, including temperature, dissolved oxygen (DO), specific conductivity, pH, oxidation reduction potential (ORP), and turbidity were measured. Table 2-3 summarizes water quality parameters measured within surface water bodies at the Site.

Similar temperature readings were recorded for each surface water body. Temperatures ranged between 15.36 and 18.06 °C. The variability can be largely attributed to time of day and depth of sample. The pH was slightly acidic (6.08 - 6.53) at all surface water bodies, with the exception of the reference location, Round Pond, where a slightly basic pH of 7.53 was recorded. Low specific conductivity readings were recorded at all surface water bodies. Richardson Pond had the highest specific conductivity with a reading of 378 microSiemens per centimeter ($\mu\text{S}/\text{cm}$). A range of 129 to 211 $\mu\text{S}/\text{cm}$ was noted at the other surface water bodies. At each surface water body, the water color was noted to be slightly stained; however, turbidity was very low at all locations, with values ranging between 1.3 to 5.26 Nephelometric Turbidity Units (NTU).

All five surface water bodies were depleted with respect to DO, with concentrations reported between 0.90 and 4.85 milligrams per liter (mg/L). The reference location, Round Pond, and Richardson Pond had the lowest DO with 0.90 and 1.35 mg/L, respectively. All bodies of water had ORP readings between 53.5 and 298 millivolts (mV). It should be noted that the bodies of water with the lowest DO concentrations had the highest ORP readings.

Low current speeds were noted (1 to 2 ft/sec) at Richardson Pond, Middlesex Canal, and Content Brook. Current speeds were estimated based on the distance that a floating object such as a leaf traveled over a specific time. No current was observed at B&M Pond and Round Pond.

SECTION 3.0 ANALYTICAL METHODS

Screening analyses for target metals (except aluminum), PAHs, and PCBs were performed off-site by the M&E team using procedures described in Appendix G of the SAP (M&E, 2004b). Microtox® screening analyses were performed by EnviroSystems, Incorporated (ESI), of Hampton, New Hampshire using the procedure provided in Appendix J of the SAP (M&E, 2004b). Grain size analysis was performed by a subcontracted geotechnical testing laboratory using the procedure described in Appendix I of the SAP (M&E, 2004b). Toxicity testing was performed by ESI using standard operating procedures (SOPs) provided in Appendix J of the SAP (M&E, 2004b). For definitive chemical analyses, the laboratories performed the analytical procedures according to the M&E Delivery of Analytical Services (DAS) specifications included in Appendix H of the SAP (M&E, 2004b). DAS specifications are developed under the EPA DAS program and are based on EPA analysis methods. Chemical analysis work was subcontracted to laboratories procured under the DAS program. DAS specifications were utilized, modified, or developed to meet the project data quality objectives (DQOs) for the sampling event. Analytical methods were selected to assess sample concentrations relative to each parameter's project action limit (PAL). The PAL for each analyte in each media was chosen based upon the lowest of chosen ecological published risk-based criteria. The PALs are listed in the analytical result tables of this report. The specific source of each individual PAL is included in Tables 6-1, 6-2, and 6-3 of the SAP (M&E, 2004b).

This section provides summaries of the analytical methods used to determine target analyte concentrations. All quality control requirements associated with the procedures are detailed in the procedures and DAS specifications referenced above. Any modifications or deviations from the DAS specifications performed by the laboratories received approval by M&E and are discussed in Section 5.0.

3.1 Sediment

The sediment sampling program was designed such that twenty-three sediment samples, including twenty site samples and three reference samples, would be collected and field-screened for toxicity, PAHs, PCBs, and target metals (except aluminum). From the results, four samples (with the possibility of a fifth) would be selected for analysis by M&E and EPA for full characterization, based on the highest screening results for three site samples and the lowest screening result for the reference sample. A fifth sediment sample would be analyzed by the laboratory if the site sample collected in the vicinity of the highest historical 4,4'-DDD concentration had not been selected based on the highest screening results.

3.1.1 Screening Analyses

3.1.1.1 Microtox® Screening. The Microtox® Acute Toxicity Test is a timed metabolic inhibition test which uses freeze-dried luminescent bacteria (*Vibrio fischeri* NRRL B-11177) to evaluate the acute toxicity of water, soil, or sediment samples. Bacterial bioluminescence is directly proportional to cellular respiration and any inhibition of cellular activity (toxicity)

results in a decreased rate of cellular respiration and a corresponding decrease in the rate of luminescence. The more toxic the sample, the greater the percent light loss from the test suspension of luminescent bacteria.

3.1.1.2 PAH Screening. The PAH RaPID Assay kit applies the principles of enzyme linked immunosorbent assay (ELISA) to the determination of PAHs and related compounds. The sample to be tested is added, along with an enzyme conjugate, to a disposable test tube, followed by paramagnetic particles with attached antibodies specific to PAHs. The PAHs (which may be in the sample) and the enzyme-labeled PAHs (the enzyme conjugate) compete for antibody binding sites on the magnetic particles. At the end of an incubation period, a magnetic field is applied to hold the paramagnetic particles (with PAHs and labeled PAH analog bound to the antibodies on the particles, in proportion to their original concentration) in the tube and allow the unbound reagents to be decanted.

The presence of PAHs is detected by adding the enzyme substrate (hydrogen peroxide) and the chromogen (3,3',5,5'-tetramethylbenzidine). The enzyme-labeled PAH analog bound to the PAH antibody catalyzes the conversion of the substrate/chromogen mixture to a colored product. Since the labeled PAHs (conjugates) were in competition with the unlabeled PAHs (sample) for the antibody sites, the color developed is inversely proportional to the concentration of PAHs in the sample.

3.1.1.3 PCB Screening. The PCB RaPID Assay kit applies the principles of ELISA to the determination of PCBs and related compounds. The sample to be tested is added, along with an enzyme conjugate, to a disposable test tube, followed by paramagnetic particles with attached antibodies specific to PCBs. The PCBs (which may be in the sample) and the enzyme-labeled PCBs (the enzyme conjugate) compete for antibody binding sites on the magnetic particles. At the end of an incubation period, a magnetic field is applied to hold the paramagnetic particles (with PCBs and labeled PCB analog bound to the antibodies on the particles, in proportion to their original concentration) in the tube and allow the unbound reagents to be decanted.

The presence of PCBs is detected by adding the enzyme substrate (hydrogen peroxide) and the chromogen (3,3',5,5'-tetramethylbenzidine). The enzyme-labeled PCB analog bound to the PCB antibody catalyzes the conversion of the substrate/chromogen mixture to a colored product. Since the labeled PCBs (conjugates) were in competition with the unlabeled PCBs (sample) for the antibody sites, the color developed is inversely proportional to the concentration of PCBs in the sample.

3.1.1.4 Target Metals Screening. The X-ray fluorescence (XRF) spectrometer uses gamma-ray bombardment to produce nuclear excitement of atoms within the test material. Upon relaxation of each excited atom, a characteristic X-ray is emitted which is proportional to the atomic number of the excited atom. By analyzing the spectral X-ray intensities, the types of elements present and their respective concentrations can be determined.

3.1.2 Full Characterization Analyses

3.1.2.1 Grain Size. The sediment samples were analyzed for grain size according to ASTM D-422-98. A quantitative determination of the distribution of particle sizes retained on the No. 10 sieve was determined by sieving using various sieve sizes ranging from 3 inch to No. 10.

3.1.2.2 Total Organic Carbon/Total Combustible Organics. The sediment samples were analyzed for total organic carbon (TOC) and total combustible organics (TCO) according to M&E DAS specification D-005.1, which is based upon the Lloyd Kahn method for TOC and ASTM D2974-87 for TCO. For TOC, the TOC analyzer converted the carbonaceous material in the samples to CO₂ by catalytic combustion. The CO₂ formed from each sample was measured by an infrared detector and was directly proportional to the concentration of organic carbonaceous material in the sample. The TOC was reported if the TCO results were less than 1 percent. The TCO was determined by measuring the ash content of the samples by combustion at 750°C.

3.1.2.3 Target Metals. M&E DAS Specification D-044.2 was used to determine concentrations of aluminum (Al), arsenic (As), barium (Ba), manganese (Mn), silver (Ag), chromium (Cr), cobalt (Co), copper (Cu), lead (Pb), vanadium (V), and zinc (Zn) in the sediment samples. Freeze-dried aliquots of the samples were digested and analyzed for the target metals by inductively coupled plasma/mass spectroscopy (ICP-MS) according to the CLP Statement of Work (SOW) ILM04.1 as modified by the DAS specification.

3.1.2.4 Pesticides and PCBs. M&E DAS Specification D-043.1 was used to determine concentrations of 4,4'-DDD and PCBs in the sediment samples. Freeze-dried aliquots of the samples were extracted and analyzed for the target compounds by gas chromatography using an electron capture detector (GC/ECD) according to the CLP SOW OLM04.3 as modified by the DAS specification.

3.1.2.5 Polynuclear Aromatic Hydrocarbons. M&E DAS Specification D-054.1 was used to determine concentrations of PAHs in the sediment samples. Freeze-dried aliquots of the samples were extracted and analyzed for the target compounds by gas chromatography/mass spectrometry (GC/MS) single ion monitoring (SIM) according to the CLP SOW OLM04.3 as modified by the DAS specification.

3.1.2.6 Toxicity. Sediment toxicity tests were conducted for the freshwater midge *Chironomus tentans*, and the amphipod *Hyaella azteca* by ESI according to ESI SOPs (M&E, 2004b), based on programs and protocols outlined in Test Methods for Measuring the Toxicity of Sediment-Associated Contaminants with Freshwater Invertebrates (ASTM, 2001), Methods for Measuring the Toxicity and Bioaccumulation of Sediment-Associated Contaminants with Freshwater Invertebrates (EPA, 2000), and Standard Methods for the Examination of Water and Wastewater, 20th Edition (APHA, 1998). *C. tentans* 10-day survival and growth toxicity tests were conducted according to ASTM method E 1706-95 and EPA method 100.5 (ESI SOP QA-1407). *H. azteca* 10-day survival and growth tests were conducted according to ASTM method E 1706-95 and EPA method 100.4 (ESI SOP QA-1406).

3.2 Surface Water

3.2.1 Total and Dissolved Target Metals

M&E DAS Specification D-004.1 was used to determine concentrations of Al, As, Ba, Mn, Ag, Cr, Co, Cu, Pb, V, and Zn, as well as calcium (Ca) and magnesium (Mg). Both field-filtered and unfiltered samples, representing dissolved and total metals, respectively, were digested and analyzed for the target metals by inductively coupled plasma/mass spectroscopy (ICP-MS) according to the CLP Statement of Work (SOW) ILM04.1 as modified by the DAS specification.

3.2.2 Alkalinity

M&E DAS Specification D-033.1 was used to determine alkalinity in surface water samples. An unaltered sample is titrated to an electrometrically determined end point of pH 4.5 with acid according to EPA Method 310.1 as modified by the DAS specification.

3.2.3 Toxicity

The surface water chronic renewal toxicity tests using the daphnid, *Ceriodaphnia dubia* and fathead minnow, *Pimephales promelas*, were performed at ESI according to ESI SOPs (M&E, 2004b), based on programs and protocols outlined in Short-Term Methods for Estimating the Chronic Toxicity of Effluents and Receiving Waters to Freshwater Organisms (EPA, 2002), and Standard Methods for the Examination of Water and Wastewater, 20th Edition (APHA, 1998). The *C. dubia* survival and reproduction assay chronic toxicity tests were conducted according to EPA method 1002.0 (ESI SOP QA-1408). The *P. promelas* survival and growth assay 7-day surface water tests were conducted according to EPA method 1000.0 (ESI SOP QA-1409).

3.3 Fish Tissue

The following sections describe methods used for analysis of fish samples collected at the Site.

3.3.1 External Examination, Weight, Length and Age

All fish were removed from the holding bin and individually examined for gross histo-pathology to detect obvious abnormalities (i.e., tumors, lesions, unusual parasitism, fin erosion, eroded gills, and other visible deformities). Each fish was also inspected for physical deformities or abnormalities, which were recorded on the field data sheet.

Following inspection, individual fish were measured for fork length (\pm 1 millimeter [mm]) and weight (\pm 0.1 gram [g]) consistent with procedures identified in the SAP (M&E, 2004b). Scales were obtained from all species except brown bullhead (*Ameiurus nebulosus*) and American eel (*Auguilla rostrata*). Dorsal spines were taken from brown bullhead. All scale and dorsal spine samples are being held at Metcalf & Eddy for potential future aging analysis if deemed necessary. American eel will not be aged due to the lack of bony structures.

3.3.2 Fish Compositing Scheme

All fish captured were rinsed with deionized ultra-filtered (DIUF) water and shipped in individual packages to the laboratory as whole body samples. M&E, in consultation with EPA, then decided which samples to analyze from each individual surface water body. Table 3-1 presents the number and mass of samples submitted for fish tissue preparation and analysis. Whenever possible, a single fish constituted one sample. If individual fish were not large enough to provide the required sample mass (approximately 50 g), multiple fish of the same species were composited at the laboratory. To the extent possible, fish of similar size and species were composited to achieve the tissue mass required for analysis. The laboratory then homogenized the whole body samples according to M&E DAS Specification D-051.1 prior to digestion for target metals and extraction for PAH and lipid content analyses.

3.3.3 Target Metals

Fish tissue samples were analyzed for target metals (Al, As, Ba, Mn, Ag, Cr, Co, Cu, Pb, V, and Zn) according to procedures outlined in M&E DAS Specification D-134. The target analytes were the same as those analyzed for sediment samples. The samples were digested and analyzed for the target metals by inductively coupled plasma/mass spectroscopy (ICP-MS) according to the CLP Statement of Work (SOW) ILM04.1 as modified by the DAS specification.

3.3.4 Polynuclear Aromatic Hydrocarbons

Fish tissue samples were analyzed for PAHs according to procedures outlined in M&E DAS Specification D-052.1. Tissue samples (approximately 5 grams) were extracted using SW-846 Method 3545 (pressurized fluid extraction). Clean-up techniques included the use of silica gel and copper. The samples were analyzed for PAHs by GC/MS using the CLP SOW OLM04.3 as modified by the DAS specification which incorporated the use of single ion monitoring (SIM) for detection of low concentrations of PAHs.

3.3.5 Lipid Content

Fish tissue samples were analyzed for total lipids according to procedures outlined in M&E DAS Specification D-058.1. The lipids analysis was performed on a split of the extract used for PAH analysis. The samples were analyzed using gravimetric methodology from EPA 823-R-95-007 *Guidance for Assessing Chemical Contaminant Data for Use in Fish Advisories* as modified by the DAS specification.

SECTION 4.0 DATA QUALITY AND DATA VALIDATION

4.1 Project Quality Objectives

Data generated during the September and October 2004 sampling events are to be used for a focused ecological risk assessment to determine the potential for adverse effects of contaminants in sediment, surface water, and biota on ecological receptors, either through direct exposure to contaminants in sediment and surface water or through indirect exposure through the food web. The following Data Quality Objectives (DQOs), as presented in the SAP (M&E, 2004b), were set for this project:

- Provide additional data for the RI/FS to support selection of a remedy to control ecological risks to the environment, including providing data to assess the risks to aquatic receptors directly exposed to metals in on-site surface water bodies;
- Assess the risks to aquatic receptors directly exposed to 4,4'-DDD, PAHs, and metals in sediment within the on-site wetlands and ponds; and
- Assess the risks to predatory birds indirectly exposed to PAHs and metals through ingestion of fish from on-site surface water bodies.

A complete discussion of project data validation and data quality is provided in Appendix F. This narrative is based on data validation memoranda submitted to EPA between November 2004 and February 2005. Tier II data validation was performed on all chemistry data, with the exception of alkalinity and TOC, associated with the September and October 2004 sampling event. The level of validation required was defined in the SAP (M&E, 2004b).

In order to determine if project DQOs were met, the quality of the actual sample and quality control results was assessed. Data quality was assessed in terms of precision, accuracy, representativeness, completeness, and comparability. For each of these terms, quality objectives were established prior to the onset of the program, and actual sample and quality control results were evaluated in relation to these quality objectives.

Data quality and test acceptability for sediment and surface water toxicity tests are discussed in Appendices G and H, respectively. Specific data validation procedures for toxicity test data are not available, however, test acceptability requirements were evaluated and protocol deviations were reviewed and reported (Appendices G and H). Results of reference toxicant evaluations conducted by the laboratory are also reported.

SECTION 5.0 DEVIATIONS FROM THE SAMPLING AND ANALYSIS PLAN

5.1 Field Methods

Field method variations to the SAP include the following:

- A dipper was used to collect surface water samples instead of filling the bottles directly, as indicated in the SAP. A dipper is a teflon-coated beaker attached to a long-handled pole, which allows collection of surface water from the shore of water bodies, and are commonly used to collect surface water. This procedure further reduced the possibility of sediment disturbances and contamination within the surface water samples.
- As noted in Section 2.1.4, fish were collected by a variety of methods during the week of September 29, 2004 through October 1, 2004. M&E, in consultation with EPA, elected to collect additional samples using baited hoop nets, trot lines, gill nets, and angling. All fish collected during the previous week were collected via electroshocking, in accordance with the SAP.

5.2 Analytical Methods

In general, analyses performed by the laboratories for this program were in accordance with the M&E DAS Analytical Specification requirements, as modified by the project specific modifications presented in the SAP (M&E, 2004b). However, additional deviations between what was performed by the laboratory and what was required by the DAS Analytical Specifications and the SAP (M&E, 2004b) were noted in several instances. These deviations were discussed with and approved by M&E prior to analysis and are listed below.

5.2.1 PAHs in Sediments

As provided in worksheet #9B in the SAP (M&E, 2004b), the laboratory had a quantitation limit (QL) of 2.0 µg/kg for most target PAHs, compared to the required 0.33 µg/kg required in DAS specification D-054.1. As the laboratory QL was consistent with the project quantitation limit of 2.0 µg/kg for each target analyte, the laboratory was approved to report sediment PAH data with a QL of 2.0 µg/kg.

5.2.2 Surface Water Toxicity Test

Review of testing procedures and data generated from surface water testing indicated one deviation from standard protocols. Sample SW-MC-01 lost two minnows from Replicate D on Day 2 due to a technician error. All statistical analysis for this replicate was, therefore, based upon the assumption that eight fish instead of ten were added at the start of testing. It is the opinion of the Study Director at ESI that this deviation had no negative impact on the outcome of the assay.

5.2.3 Method Detection Limit Studies for Tissue Analyses

The laboratory indicated that tissue method detection limit (MDL) studies are difficult and not performed on a routine basis. The DAS methods for PAH and metals analysis of tissue samples (D-052.1 and D-134, respectively) required that an MDL study be performed in the previous nine months. The laboratory had performed MDL studies several years ago, and this was deemed sufficient by the project chemist for meeting the objectives of the MDL studies.

5.2.4 Analysis of Tissue Standard Reference Materials

The laboratory indicated that freeze dried standard reference materials (SRMs) analyzed in conjunction with samples had matrix issues that overloaded the analytical systems, causing analytical problems that were not indicative of analysis of the other field samples. The laboratory was approved to reduce the sample size of co-analyzed SRMs such that the SRM-specific overloading issues were minimized.

SECTION 6.0 RESULTS

This section summarizes the results for sediment, surface water, and fish tissue sampling conducted by M&E during September and October 2004.

6.1 Sediment

Twenty-three sediment samples underwent screening analyses, five of which were selected for full characterization. The results are presented below.

6.1.1 Screening Analyses

6.1.1.1 Microtox® Results. The Microtox® results were used in conjunction with the other screening analyses to select sediment samples for full characterization analysis. Microtox® utilizes a reconstituted bioluminescent marine bacteria, *Vibrio fischeri*, where a reduction in light output serves as a measure of toxicity, and percent effect, or reduction in light, is quantified at 5 and 15 minutes. In two samples collected from B&M Pond (SED-05 and SED-08), approximately 60% effect was measured at 5 minutes. SED-05 was selected for full characterization. From the West Middlesex Canal, two sediment samples (SED-10 and SED-11) showed approximately 50% effect at 15 minutes; SED-11 was one of the samples chosen for full characterization. Three of the four samples from Content Brook (SED-01, SED-02, and SED-04) showed percent effects ranging from 28% to 37% at 5 minutes, including SED-01 which was also selected for full characterization. Lower percent effects were observed in samples from the Unnamed Brook (SED-17, SED-18, SED-19, and SED-20), Richardson Pond (SED-13, SED-14, and SED-15), and Round Pond (reference samples SED-21, 22, and 23), with the exception of sample SED-16 from Richardson Pond. Differences in percent effect at 5 and 15 minutes are hypothesized due to varying response times for different chemicals, as well as adaptation on behalf of the bacteria. The sediment toxicity report generated by ESI including Microtox® data is provided in Appendix G.

6.1.1.2 PAH Screening Results. The screening results for total PAHs were corrected for dry weight and are summarized in Table 6-1. Information used to determine dry weight results is provided in Appendix I. Total PAH concentrations were detected in all samples, with an average concentration of 51.1 mg/kg dry weight (wt.) in the 23 samples. The highest concentrations were detected in samples SED-05 (161.6 mg/kg dry wt.) and SED-07 (163.13 mg/kg dry) from B&M Pond, SED-12 (156.8 mg/kg dry wt.) from the West Middlesex Canal, and SED-18 (116.84 mg/kg dry wt.) from the Unnamed Brook.

PAH concentrations were 20 mg/kg or less in Content Brook and at Round Pond, the reference location. Of the four sediment samples from B&M Pond, two had total PAHs

greater than 160 mg/kg dry wt., and the other two samples had total PAH concentrations less than 20 mg/kg dry wt. Samples from the West Middlesex Canal had total PAH concentrations ranging between 47.36 and 156.8 mg/kg dry wt., with the exception of sample SED-11 (6.1 mg/kg dry wt.). PAH detections within samples from the Unnamed Brook ranged between 28.24 and 116.84 mg/kg dry wt. In Richardson Pond, total PAH concentrations ranged between 7.69 and 59.36 mg/kg dry wt.

6.1.1.3 PCB Screening Results. The screening results for total PCBs were corrected for dry weight and are summarized in Table 6-1. Information used to determine dry weight results is provided in Appendix I. In all sediment samples, total PCB concentrations were below the detection limit, specific to percent solids of the sample.

6.1.1.4 Target Metals Screening Results. Screening analysis was performed for ten metals for the sediment samples collected, including arsenic, barium, cobalt, copper, chromium, lead, manganese, silver, vanadium, and zinc. The results are summarized in Table 6-1. An XRF screening form providing additional information about the analysis is provided in Appendix I.

Arsenic was detected in 10 of the 23 sediment samples collected, with results ranging from 40.6 to 334 mg/kg, and detections occurring within at least one sample collected from each area, except the reference location, Round Pond. The highest arsenic concentrations were recorded in samples SED-01 (334 mg/kg) and SED-14 (317 mg/kg), from Content Brook and Richardson Pond, respectively. Three of four samples from Content Brook had detectable arsenic concentrations.

Lead concentrations were detected in 22 of the 23 sediment samples collected. The average lead concentration in sediment was 285 mg/kg. Lead was detected at all areas, including the reference pond. The highest concentrations were in samples SED-05 (822 mg/kg) from B&M Pond, SED-11 (929 mg/kg) from West Middlesex Canal, and SED-17 (914 mg/kg) from the Unnamed Brook. The sediment samples from Content Brook and Round Pond, the reference location, contained lead at concentrations less than 200 mg/kg.

Detectable concentrations of barium were recorded in 18 of the 23 sediment samples collected. The detected concentrations ranged between 83.7 and 497 mg/kg, with the highest barium concentration in SED-20 collected from the Unnamed Brook. Copper was detected in 4 of 23 total samples, with detected concentrations ranging between 121 and 930 mg/kg. These samples were collected from B&M Pond, the West Middlesex Canal, and the Unnamed Brook. Manganese was found at detectable concentrations in six sediment samples. The highest manganese concentrations were detected in B&M Pond samples SED-06 and SED-07 (839 and 3,120 mg/kg, respectively). All sediment samples collected from the reference pond contained detectable manganese concentrations (333 to 581 mg/kg). Zinc was detected in 21 of 23 sediment samples, with an average concentration of 370 mg/kg. The highest zinc concentrations were detected at locations

SED-05 (3,870 mg/kg) collected from B&M Pond and SED-13 (1,090 mg/kg) collected within the Richardson Pond wetland. Chromium was only detected in sample SED-19 collected from the Unnamed Brook (511 mg/kg). Cobalt, silver, and vanadium were not detected at concentrations above their specific detection limit in any sample.

6.1.2 Full Characterization Analyses

In consultation with EPA, five sediment samples were selected for full characterization analyses, including four that were based on either elevated field-screening results (three site samples) or the lowest screening result (one reference sample), as well as one location within B&M Pond that had been the location of the highest historical 4,4'-DDD detection. Since the samples were screened for toxicity, PAHs, PCBs, and ten target metals, there were numerous variables to consider within the screening results to select samples for full characterization analyses. In addition, the spatial separation of full characterization samples across the site was desired, to be able to better characterize site-wide risks during the focused ecological risk assessment.

Sediment samples selected for full characterization include SED-01 (within the Content Brook Area), SED-05 (within B&M Pond), SED-11 (within the West Middlesex Canal), SED-18 (within the Unnamed Brook), and SED-22 (within the reference area - Round Pond). No samples were selected from Richardson Pond for full characterization. The rationale for the selection of sediment samples for full characterization is provided in Table 6-2. Historical data, as well as the field-screening results, were considered during the selection of samples for full characterization. The sediment samples not selected for full characterization are being held by the laboratories in a frozen state should additional samples require full characterization.

Samples selected for full characterization were analyzed for grain size, toxicity, and chemical analyses including TOC, target metals, 4,4'-DDD, PCBs, and PAHs. Sample aliquots for target metals, 4,4'-DDD, PCBs, and PAHs were freeze-dried upon receipt at the laboratory if the percent moisture was measured to be 50% or more. For grain size, toxicity, and TOC analyses, samples were not freeze-dried prior to analysis. Grain size results are summarized in Table 6-3. Results for the chemical analyses are provided in Table 6-4. Toxicity testing results are provided in the report generated by ESI in Appendix G. Analytical results tables are included in Appendix J. The grain size analysis report is included in Appendix K.

6.1.2.1 Grain Size. The grain size analysis confirmed that the sediments were predominantly sand (69.6% to 88.1 %) with smaller fractions of silt and clay (4.3% to 28.4%) and gravel (0.0% to 16.6 %). Large particulate organic matter (such as sticks, roots, and plant stems) are typically removed by the laboratory, if not already removed during the collection of the sample, prior to the sieve analysis. However, smaller organic matter, such as leaves, undergoes the sieve analysis, and thus is captured on the appropriately-sized sieve, contributing toward the total weight retained on that sieve.

6.1.2.2 Total Organic Carbon. Organic material was observed and recorded in each of the samples. The TOC content within the four site samples ranged between 16.1 and 32.3%. However, for the field duplicate of SED-05, which was called SED-25, a TOC value of 272% was reported. Although this value was not rejected during data validation, the usability and reliability of this value is considered questionable. The TOC content in the sediment sample from Round Pond, the reference location, was reported at 86.5%.

6.1.2.3 Target Metals. Several target metals, including arsenic, chromium, copper, lead, manganese, silver, and zinc, were detected at concentrations exceeding PALs in one or more site samples. Within the reference sample, SED-22, lead was estimated at a concentration equivalent to the PAL. The sediment sample collected from B&M Pond (SED-05, field duplicate SED-25) contained the highest concentrations of each of the metals except arsenic and lead, with an exceedance of PALs for six metals (seven within the duplicate). As, Ba, Cr, Co, Cu, Pb, and Zn concentrations in SED-05 exceeded reference metal concentrations by one to two orders of magnitude. The lowest metals concentrations of the site locations were detected in the West Middlesex Canal sediment sample (SED-11), with concentrations similar to those in the reference pond sample. The sediment sample from Content Brook (SED-01) contained the highest concentrations of arsenic (360 mg/kg) and manganese (1,600 mg/kg) of the site samples. In addition, at location SED-01, copper and lead were detected at concentrations slightly above their respective PALs. For sediment sample SED-18, six metals exceeded their PALs.

As discussed in Appendix F, the equipment blank contained detectable levels of barium, manganese, and zinc. Because the equipment blank is a different matrix than the sediment samples, the sample data was not qualified during data validation, but was flagged with an 'EB' to indicate there may be some contribution to the sample result from equipment blank contamination. Although the impact on the sample result from the contamination seen in the equipment blank cannot be easily quantified, it would be reasonable to assume that any contamination would impact all associated samples in a fairly consistent manner. Therefore, in an effort to gauge the effects of possible contamination, the lowest result for a given analyte in the sample set can be used to gauge the maximum possible contribution caused by the contamination seen in the equipment blank. For other samples, any contribution from the contamination seen in the equipment blank would become less substantial as the detected concentration in the sample increases. For a sample with a concentration an order of magnitude or more higher than the lowest result, it is reasonable to assume that any impact from the contamination seen in the equipment blank becomes less. This may not be the case, but it provides an estimation of how reported contamination in the equipment blank may have affected a sample's reported concentration.

For barium, the lowest detection was 27 mg/kg as measured in SED-22. Although it cannot be quantified, the potential exists that this result may have been impacted by the contamination that was detected in the equipment blank. Since the barium concentration

at SED-11 was reported as 28 mg/kg, this result may be similarly affected by the contamination seen in equipment blank. Assuming a worst case scenario, where the contamination seen in the equipment blank potentially contributes about 27 mg/kg to the sediment sample result, SED-18, with a concentration of barium detected at 110 mg/kg, may be less affected than SED-11 and SED-22. The concentrations of barium within all other samples, including SED-01 and SED-05 (SED-25 duplicate) may be the least affected, since the concentrations were approximately one order of magnitude higher than the lowest concentration detected.

Likewise, the lowest detection of manganese within the sediment samples was 220 mg/kg estimated in SED-11. Assuming the worst case scenario that the total manganese concentration within this sample is due to equipment blank contamination, sediment samples SED-05, SED-18, and SED-22 may be affected, while SED-01 may be less affected.

The lowest detection for zinc which also had equipment blank contamination was 21 mg/kg (SED-11). Assuming the same rationale as above, the results for SED-11 and SED-22 may be affected, SED-01 and SED-18 may be less affected, and SED-05 may be the least affected.

6.1.2.4 Pesticide/Polychlorinated Biphenyls. The highest concentrations of 4,4'-DDD, Aroclor-1254, and Aroclor-1260 were detected in SED-05 (and duplicate SED-25), the sediment sample collected within B&M Pond. The average concentration of 4,4'-DDD in the sediment sample (SED-05) and its field duplicate (SED-25) was 92.5 µg/kg, which is higher than the PAL of 2 µg/kg. Concentrations of Aroclor 1254 and 1260 also exceeded their respective PALs, at average concentrations of 2,695 and 1940 µg/kg. Lower concentrations of 4,4'-DDD were reported in SED-01 (2.69 µg/kg), which was collected from Content Brook, and SED-18 (17.9 µg/kg) collected from the Unnamed Brook, both of which exceeded the PAL for 4,4'-DDD (2 µg/kg). These two locations (SED-01 and SED-18) also had exceedances of the Aroclor-1260 PAL (5 µg/kg), with estimated concentrations of 11.5 µg/kg and 20.1 µg/kg, respectively. There were also exceedances of 4,4'-DDD and Aroclor-1260 at the reference location, SED-22, with concentrations detected at 14.5 µg/kg and 13.7 µg/kg, respectively. For SED-11, the concentration of 4,4'-DDD was rejected during data validation due to poor dual column precision. Further details on the rejection are provided in Appendix F.

It should be noted that in some instances, the detection limit for specific PCB Aroclors was elevated in relation to the PAL due to sample dilution, needed to analyze other compounds within the sample.

6.1.2.5 Polynuclear Aromatic Hydrocarbons. The sediment sample collected from B&M Pond, SED-05, had the highest concentrations of PAHs, with PAL exceedances occurring for 17 of 25 PAH compounds. The total PAH concentration detected in the

B&M Pond sediment sample (SED-05 and duplicate SED-25) was 173,860 µg/kg. For PAH compounds, the concentration was two to three orders of magnitude greater than that from the reference pond sample. A total PAH concentration of 12,416 µg/kg was detected in SED-18, collected from the Unnamed Brook. PALs were exceeded for 17 PAH compounds within this sample. Lower concentrations of PAHs were detected in SED-11, collected from the West Middlesex Canal, and SED-01, collected within Content Brook, with the concentrations on the same order as SED-22, the reference sample. However, there were PAL exceedances for four compounds within SED-01. For SED-11 and SED-22, there were no PAL exceedances. The total PAH concentrations in SED-01, SED-11, and SED-22 were 1,955 µg/kg, 627 µg/kg, and 933 µg/kg, respectively. As discussed in Appendix F, the equipment blank contained detectable levels of naphthalene, 1-methylnaphthalene, phenanthrene, 1-methylphenanthrene, fluoranthrene, pyrene, and benzo[b]fluoranthene. Because the equipment blank is a different matrix than the sediment samples, the sample data was not qualified during data validation, but was flagged with an 'EB' to indicate there may be some contribution to the sample result from equipment blank contamination. Although the impact on the sample result from the contamination seen in the equipment blank cannot be easily quantified, it would be reasonable to assume that any contamination would impact all associated samples in a fairly consistent manner. Therefore, in an effort to gauge the effects of possible contamination, the lowest result for a given analyte in the sample set can be used to gauge the maximum possible contribution caused by the contamination reported in the equipment blank. For other samples, any contribution from the contamination seen in the equipment blank would become less substantial as the detected concentration in the sample increases. For a sample with a concentration an order of magnitude or more higher than the lowest result, it is reasonable to assume that any impact from the contamination reported in the equipment blank becomes less. This may not be the case, but it provides an estimation of how reported contamination in the equipment blank may have affected a sample's reported concentration.

As shown on Table 6-4, the lowest concentrations of these compounds were detected in either SED-11 or SED-22. Although unquantifiable, the potential exists that these results may have been impacted by the contamination that was detected in the equipment blank. Assuming a worst case scenario, where the contamination reported in the equipment blank potentially contributes the lowest detected concentrations to the sediment sample results, in general, the results for the seven PAHs listed above within SED-11 and SED-22 may have been affected, within SED-01 may have been less affected, and within SED-05 may have been the least affected.

6.1.2.6 Sediment Toxicity. In ten-day toxicity tests, average survival of the midge larvae (8 replicates), *Chironomus tentans*, in the sediment from the reference location was 77.5%, with a range of 70 to 100% (Table 6-5; Table 2 of sediment lab report in Appendix G). The highest chironomid growth was observed at SED-01 (Content Brook) at 2.21 mg/larvae, which exceeded growth in both the reference (SED-22) and lab control

(Table 6-6; Table 3 of sediment lab report in Appendix G). Both survival and growth of individuals in the reference sediment, SED-22, were not statistically different from the laboratory control. The survival of midge larvae in the sediment sample collected from the West Middlesex Canal (SED-11, 71.3%) was significantly lower than the laboratory control, but not when compared to the reference location sediment (Table 6-5). Midge larvae maintained in sediment collected from B&M Pond (SED-05), the West Middlesex Canal (SED-11), and the Unnamed Brook (SED-18) showed statistically lower growth than both the laboratory control and reference location sediment (Table 6-6).

At the end of the 10-day exposure period, mean survival in the laboratory control sediment was 83.8%. Larvae recovered from the laboratory control sediment had a mean ash free dry weight of 2.03 mg/larvae. The minimum acceptable criteria for survival in the laboratory control is 70% and the minimum acceptable criteria for growth is a mean ash free dry weight of 0.48 mg/larvae. These data indicate that the organisms were healthy and not stressed by handling.

Chironomid survival in the project reference sediment (SED-22) at the end of the 10-day exposure period was 77.5%, with individual replicates ranging from 70 to 100%. Surviving midge larvae had a mean ash free dry weight of 1.84 mg/larvae. Survival and growth of midge larvae maintained in the reference sediment was not statistically less than that observed in the laboratory control.

With eight replicates, mean 10-day survival of amphipods, *Hyalella azteca*, observed in the reference sediment was 92.5%, which was statistically less than the 100% survival in the laboratory control (Table 6-7; Table 4 of sediment lab report in Appendix G). However, growth was not statistically lower in the reference sample as compared to the laboratory control sample (Table 6-8; Table 5 of sediment lab report in Appendix G). Survival of amphipods maintained in sediment samples from Content Brook (SED-01), B&M Pond (SED-05), and the West Middlesex Canal (SED-11) ranged from 87.5% to 92.5%, but were statistically lower than the laboratory control (100%). These samples did not show survival rates of amphipods statistically lower than the reference sample. The survival of amphipods on sediment from the Unnamed Brook (SED-18) was 7.5% and statistically lower than both the reference and control samples. Growth data of amphipods in sediment from the four site locations were not statistically lower than the laboratory control or the reference location.

At the end of the 10-day exposure period, mean survival in laboratory control sediment was 100%. Amphipods, recovered from laboratory control sediment, had a mean dry weight of 0.080 mg/amphipod. The dry weight of a representative group of amphipods at the start of the assay was 0.030 mg/individual. The minimum test acceptability criteria for survival in the laboratory control is 80%. The minimum acceptable criteria for growth is a demonstration of increased dry weight after 10 days exposure. These data indicate that the organisms were healthy and not stressed by handling.

Amphipod survival in the reference sediment (SED-22) at the end of the 10-day exposure period was 92.5% survival, with individual replicates ranging from 80 to 100%. Surviving amphipods had a mean dry weight of 0.078 mg/amphipod. Survival, but not growth, of the amphipods observed in the reference sediment was statistically less than that observed in the laboratory control.

Review of water quality parameters collected at the beginning and end of the assays documented a greater than 50% change in the alkalinity, ammonia, hardness, and conductivity levels of the overlying water between the start and end of the chironomid assay. A similar deviation was noted for the alkalinity and ammonia levels in the amphipod assay. Review of the water quality data collected on the renewal water used in the assays documented that, prior to being added to the test chambers, there was less than a 50% change in concentration for the identified parameters between the start and end of the assay. The changes reported in the test chambers were interpreted by the lab as reflecting the influence of the substrate on the water quality parameters. Measured ammonia concentrations in overlying water were generally less than 2 mg/L. The highest observed value was 23 mg/L in SED-01, which dropped over the 10-day period to 0.2 mg/L. Survival and growth were high in this sample. The observed deviations do not appear to have affected the test results.

6.2 Surface Water

Surface water results for total and dissolved target metals and alkalinity are provided in Table 6-9 and described below. Toxicity testing results are summarized in Tables 6-10 through 6-13. The surface water toxicity laboratory report generated by ESI is included in Appendix H.

6.2.1 Total and Dissolved Target Metals

PAL exceedances occurred for barium and manganese within all samples for both the total and dissolved analyses. In addition, total arsenic was estimated at concentrations greater than or equal to the PAL within all samples collected within Richardson Pond (SW-RP-01, -02, and -03) and one sample collected within Content Brook (SW-CB-02). A total aluminum PAL exceedance also occurred within this Content Brook sample (SW-CB-02).

Aluminum was detected within all five water bodies, with the highest average concentrations reported in Content Brook (98.8 µg/L). Slightly more than half of the total aluminum concentration was as dissolved aluminum within samples collected from the West Middlesex Canal (SW-MC samples), Content Brook (SW-CB samples), and B&M Pond (SW-BM samples). For samples collected within remaining areas, including Richardson Pond (SW-RP samples) and Round Pond (SW-RF samples), the majority of the aluminum detected was in the dissolved phase. Arsenic concentrations ranged from 1.1 to 3.4 µg/L, with concentrations almost entirely in the dissolved phase reported in samples collected from the West Middlesex Canal, B&M Pond, and

Round Pond. Total arsenic concentrations exceeded PALs within one or more samples collected from Richardson Pond and Content Brook. Total lead was detected at each body of water, with average concentrations ranging between 0.26 and 1.6 µg/L. Approximately half of the total lead detected was in the dissolved phase. Concentrations of total and dissolved lead detected in Round Pond were higher than those detected from Richardson Pond.

Barium, calcium, magnesium, and manganese were detected in each body of water. For barium, the average total concentrations were reported between 18.4 and 39.6 µg/L, which are all above the PAL of 3.9 µg/L. The average total calcium concentrations ranged between 8,963 and 13,200 µg/L. The range of average total magnesium in the surface water samples was 1,677 to 3,167 µg/L. Average total manganese concentrations were between 132 and 297 µg/L, all of which are above the manganese PAL of 80 µg/L. Similar to arsenic, the dissolved phase accounted for nearly all of the total concentrations of barium, calcium, magnesium, and manganese. Trace concentrations of zinc were measured in one or more samples collected from each body of water except Richardson Pond. Copper was estimated at concentrations slightly above the detection limit in all samples collected from B&M Pond. Chromium, cobalt, silver, and vanadium were not detected in any surface water samples.

6.2.2 Alkalinity

Total alkalinity concentrations did not vary significantly in the samples collected at the Site. The average concentrations for the four site locations were 26.0 mg/L as calcium carbonate (CaCO₃) in B&M Pond, 31.6 mg/L as CaCO₃ in West Middlesex Canal, 34.9 mg/L as CaCO₃ in Richardson Pond, and 36.1 as CaCO₃ in Content Brook. The lowest average alkalinity was measured in the surface water of Round Pond, with a value of 18.8 mg/L as CaCO₃.

6.2.3 Toxicity

Three sets of assays for daphnid, *Ceriodaphnia dubia*, were performed and survival varied between 70% and 100% (Table 6-10; Tables 2 and 4 of surface water laboratory report in Appendix H). Due to holding time considerations, samples were analyzed as they were received with each group of samples receiving its own laboratory control treatment. From statistical comparison with the laboratory control, Round Pond, the reference location was the only body of water where survival of *C. dubia* was significantly reduced. Since survival was lowest at the reference location, comparisons of the other sites to the reference data all showed greater survival, and statistical comparisons to detected differences were not performed.

Reproduction, measured as the number of juveniles produced per female, ranged from 21.9 to 33.2 juveniles per female (Table 6-11; Tables 3 and 5 of surface water laboratory report in Appendix H). Reproduction was lower in samples from Richardson Pond and Round Pond, the reference location. However, comparison of reproduction data for *C. dubia* against Round Pond showed that reproduction in the other project sites was not statistically different from that observed at Round Pond. The two surface water bodies having the lowest dissolved oxygen

(DO) concentrations in the surface water were Richardson Pond and Round Pond, with 1.35 and 0.90 mg/L, respectively.

Laboratory controls met test acceptability criteria for both survival and reproduction endpoints for *C. dubia* assays. Laboratory control survival was 100% in each series. Reproduction in the laboratory controls ranged from 28.4 to 33.7 juveniles per female. Minimum test acceptability criteria require 80% survival, mean production of 15 juveniles/female, and production of 3 broods by at least 60% of control animals (EPA, 2002). These results are an indication of healthy test organisms.

Survival rates ranged from 57.5% to 100% in assays performed with minnows, *Pimephales promelas* (Table 6-12; Tables 6 and 8 of surface water laboratory report in Appendix H). Survival in the sample from the West Middlesex Canal (57.5%) was statistically less than both the laboratory control and the reference pond. Growth, measured as mean dry weight, ranged from 0.346 to 0.534 mg/fish (Table 6-13; Tables 7 and 9 of surface water laboratory report in Appendix H). Growth was not significantly lower in any of the site samples when compared to the laboratory controls. However, minnow growth in water from Content Brook and Middlesex Canal was statistically less than Round Pond, the reference location.

Although statistical analyses have been performed against both control and reference samples for the surface water toxicity tests, there is some uncertainty in these comparisons. Due to holding time considerations, surface water samples were analyzed as they were received with each group of samples receiving its own laboratory control treatment. There is an added uncertainty in the statistical results for the surface water toxicity tests when the comparisons to reference samples were calculated since these samples groups were run on different days using different laboratory controls. The laboratory data indicate that the control run with the reference pond (RF-01) showed higher growth rates during the test than any other sample group (Table 6-13). This makes the statistical significance of the comparison of Content Brook and Middle sex Canal to the reference pond questionable.

Laboratory controls met test acceptability criteria for both survival and growth endpoints for *P. promelas* assays. Laboratory control survival was 87.5 to 100%. Growth ranged from 0.448 to 0.482 mg/fish in laboratory controls. Minimum test acceptability criteria require 80% survival and mean dry weight of 0.250 mg/fish (EPA, 2002). These results are an indication of healthy test organisms.

Review of testing procedures and data generated from surface water testing indicated one deviation from standard protocols. Sample SW-MC-01 lost two minnows from Replicate D on Day 2 due to a technician error. All statistical analysis for this replicate was, therefore, based upon the assumption that eight fish instead of ten were added at the start of testing. It is the opinion of the Study Director at ESI that this deviation had no negative impact on the outcome of the assay.

6.3 Fish Tissue

During the fish sampling event, a total of 146 fish were collected, consisting of 12 species: bluegill (*Lepomis macrochirus*), pumpkinseed (*Lepomis gibbosus*), yellow perch (*Perca flavescens*), largemouth bass (*Micropterus salmoides*), black crappie (*Pomoxis nigromaculatus*), brown bullhead (*Ameiurus nebulosus*), yellow bullhead (*Ameiurus natalis*), golden shiner (*Notemigonus crysoleucas*), longnose dace (*Rhinichthys cataractae*), American eel (*Auguilla rostrata*), redbfin pickerel (*Esox americanus*), and chain pickerel (*Esox niger*) (Table 6-14). Golden shiner and longnose dace were the most abundant fish species collected and pumpkinseed and chain pickerel were the least common.

All fish collected during this study, except the American eel, are not known to migrate over significant distances and may be considered local residents of the surrounding study area. Due to the migratory nature of the American eel, contaminant levels found in these individuals may not be representative of the study area. Fish feeding behavior, which varies between species, was not considered during discussion of the tissue contaminant results.

Fish analyses included an external examination, measurements of weight and length, and laboratory analyses for target metals, PAHs, and lipid content.

6.3.1 External Examination, Length, and Weight

Individual length (mm), weight (g), and external pathology was determined for each fish sampled and is summarized in Table 6-14. On average, the largest fish, both in length and weight, were collected from Round Pond, the reference location. The length of the fish from Round Pond ranged from 45 mm (bluegill) to 424 mm (American eel). The weight of the fish from Round Pond ranged from 0.7 g (yellow perch) to 474 g (brown bullhead). Round Pond also contained the highest diversity of species, with the black crappie, chain pickerel, pumpkinseed, and yellow perch only being captured from Round Pond. Richardson Pond contained the least diverse fisheries community with golden shiner and brown bullhead being the only two species encountered. No single fish species was collected at all sample locations. However, with the exception of Content Brook, brown bullhead were collected at all other locations. In Content Brook, eight yellow bullhead were captured, which are a very similar species to the brown bullhead occupying similar ecological niches.

All fish appeared to be in excellent physical condition with no major abnormalities or parasites, with the exception of one golden shiner (collected from Round Pond) which had parasites. Three brown bullhead collected from B&M Pond had minor caudal hemorrhaging. Fish collected from Richardson Pond all appeared normal with the exception of two golden shiner specimens which had minor pelvic and caudal hemorrhaging.

6.3.2 Target Metals

Analysis of the 11 target metals was conducted on twenty site and five reference fish composite samples collected. Metals results are summarized in Table 6-15. The PAL for lead was exceeded in two samples, CB-BH-4 and CB-AE-1, collected from Content Brook, and one sample, MC-AE-1, collected from the West Middlesex Canal. In addition, copper was estimated at a concentration equivalent to the PAL (13 mg/kg) in sample CB-BH-4 collected from Content Brook.

Overall, the highest average concentrations of most metals, including aluminum, arsenic, barium, chromium, cobalt, copper, and manganese, were detected in fish tissue samples collected from B&M Pond. However, there were no PAL exceedances from any samples collected from this location. The highest average concentrations of lead, silver, and zinc were detected in samples collected from Content Brook. Average vanadium concentrations were similar in tissue samples collected from all water bodies, including the reference pond. The fish tissue samples from the reference pond, as well as Richardson Pond, generally had low concentrations of metals. Samples from the West Middlesex Canal had metals concentrations higher than the reference pond, although concentrations of chromium, cobalt, vanadium, and zinc were similar to those detected in Round Pond.

In evaluating the metals data in bullheads only, samples collected from B&M Pond had higher concentrations than the reference samples and the other site samples. Bullheads collected from Content Brook and Middlesex Canal also had aluminum, zinc, and manganese levels greater than the reference samples.

6.3.3 Polynuclear Aromatic Hydrocarbons

There were exceedances of the acenaphthene PAL in four composite tissue samples collected from B&M Pond, one sample collected from Content Brook, and one sample collected from the West Middlesex Canal. In addition, there was one exceedance of the phenanthrene PAL, which occurred in BM-BH-1 collected from B&M Pond. PAH results are summarized in Table 6-15.

Total PAH concentrations for whole body samples ranged from non-detect to 66.8 µg/kg wet weight. Generally, the highest concentrations of PAHs in fish tissue for all species were in fish collected from B&M Pond and West Middlesex Canal. Fish collected from Content Brook and Richardson Pond had lower concentrations of PAHs. The PAH concentrations in fish collected from the reference location were non-detect or estimated below the detection limit.

6.3.4 Lipid Content

Total lipid content for each fish composite sample is summarized in Table 6-15. Percent lipids varied between 0.51% and 7.9%. The highest % lipids were in the American Eel specimens (1.7%, 5.2%, and 7.9%). The average lipid concentration for bullheads was 1.42% and ranged from 0.51% to 2.8%. Lipid content of the three green shiners collected ranged between 1.6% and 2.8%.

6.3.5 Chemistry Interrelationships

Relationships between contaminant concentrations and % lipids in fish were evaluated to determine the likelihood of high contaminant levels relative to high lipid content. When the data from all samples collected are pooled, total PAH concentrations appear to be independent of percent lipids (the R^2 value equals 0.004). However, in B&M Pond, a positive relationship between percent lipids and total PAHs was observed (the R^2 value equals 0.94). In Content Brook, the total PAH concentration increased slightly with percent lipids, but the correlation was weak (the R^2 value equals 0.41). Figure 6-1 demonstrates the relationship between total PAHs and percent lipids, by water body.

A strong positive correlation is also apparent in B&M Pond between % lipids and total PAH concentrations in bullheads (the R^2 value equals 0.996), as shown in Figure 6-2. There is no relationship between percent lipids and PAH concentrations in bullheads in other on-site water bodies. These comparisons are based on small data sets within each location. Therefore, these relationships may not extrapolate to larger population sets.

SECTION 7.0 CONCLUSIONS

During September and October 2004, M&E conducted a sampling program at the Iron Horse Park Superfund Site - OU-4 in North Billerica, Massachusetts, for U.S. Environmental Protection Agency (EPA) Region I. Sediment, surface water, and fish samples were collected from various site areas, including Content Brook, the West Middlesex Canal, B&M Pond, the Unnamed Brook, and Richardson Pond, as well as Round Pond, a reference area. Data collected will be used in a focused ecological risk assessment for the Site.

As specified in the *Sampling and Analysis Plan (Field Sampling Plan and Quality Assurance Project Plan) for Remedial Investigation/Feasibility Study Addendum (OU-4) - Revision 00, Iron Horse Park Superfund Site, North Billerica, Massachusetts* (M&E, 2004b), Tier II data validation was performed on all the analytical chemistry data, except for TOC and alkalinity, which was validated to Tier I. Grain size and toxicity data were not formally validated. The required level of validation was met for all matrices.

7.1 Summary of Results

7.1.1 Sediment

Twenty-three sediment samples were collected within the Site and reference areas and screened for toxicity, PAHs, PCBs, and target metals, excluding aluminum. Based on the screening analysis results, four sediment samples, including three site samples and one reference sample, were selected for full characterization analyses, including grain size, toxicity, TOC, 4,4'-DDD, PCBs, PAHs, and target metals. An additional sample, which had been collected in the vicinity of the highest historical 4,4'-DDD concentration, was submitted for full characterization analyses since it had not been selected based on screening results, and full characterization of this sample was desired.

The analytical results indicated instances where concentrations exceeded the PALs for 4,4'-DDD, PCBs, PAHs, and target metals. The exceedances were most numerous for samples collected from B&M Pond (SED-05 and its field duplicate SED-25) and the Unnamed Brook (SED-18). Fewer PAL exceedances occurred for the Content Brook sediment sample (SED-01), although the PAL was still exceeded for ten compounds/analytes. There were no PAL exceedances for the West Middlesex Canal sample (SED-11). The sample collected within the reference area, Round Pond, had two PAL exceedances (4,4'-DDD and Aroclor-1260).

Toxicity test results with the midge, *Chironomus tentans*, showed a small reduction in survival of larvae exposed to West Middlesex Canal sediment (SED-11) as compared to survival of the laboratory control. However, the reduction in survival was not significant when compared to the survival of organisms from the reference sediment sample. Toxicity test results also showed a

small reduction in growth of midges exposed to sediment from SED-05, SED-11, and SED-18 when compared to the growth of organisms from both the laboratory control and reference sediment sample.

For toxicity tests with the amphipod, *Hyalella azteca*, results showed that after 10 days of exposure, survival of amphipods maintained in sediments from samples SED-01, SED-05, SED-11, and SED-18 was statistically less than survival of the laboratory control. However, when statistical comparisons were made against the reference sample, the sediment from sample SED-18 was the only sample with significantly lower survival. Analysis of growth data showed no toxicity to amphipods maintained on all four sediment samples as compared to both the laboratory control and the reference sediment.

7.1.2 Surface Water

Surface water was collected in triplicate from five different water bodies, including Content Brook, the West Middlesex Canal, the Unnamed Brook, Richardson Pond, and the reference area, Round Pond. Surface water analyses conducted include total and dissolved target metals, alkalinity, and toxicity testing.

There were PAL exceedances for total and dissolved barium and manganese within all samples collected, including the samples collected from Round Pond. In addition, total arsenic concentrations exceeded the PAL in samples collected from Richardson Pond. In addition, the total arsenic concentration was estimated at a value equivalent to the PAL in one sample collected from Content Brook. Total aluminum also exceeded the PAL in the Content Brook sample.

Toxicity test results with the daphnid, *Ceriodaphnia dubia*, showed toxicity (i.e., lower survival) at the reference location (Round Pond) when compared to the laboratory control. No reduction in survival of daphnids was observed at any of the site surface water samples. Reproduction data indicated statistically significant negative impacts on daphnid reproduction in water from SW-RP-01 when evaluated against the associated laboratory control, but no significant toxicity when compared to the reference sample (SW-RF-01).

Toxicity test results with the minnow, *Pimephales promelas*, indicated that samples collected from the West Middlesex Canal (SW-MC-01) displayed lower survival than the laboratory control and the reference sample. However, no impairments of growth of minnows compared to either laboratory controls or the reference sample was observed, including samples from the West Middlesex Canal.

7.1.3 Fish Tissue

A total of 146 fish were collected for this study, which were later composited into 25 samples for analysis. All collected fish underwent an external examination and were weighed and length measured. Fish tissue analyses conducted include target metals, PAHs, and percent lipids.

Metals detected at concentrations exceeding their PALs include lead (in two samples collected from Content Brook and one sample collected from the West Middlesex Canal) and copper (estimated at a value equivalent to the PAL in one sample collected from Content Brook). There were two PAHs for which PALs were exceeded (acenaphthene and phenanthrene). Samples for which the acenaphthene concentration exceeded its PAL include all four samples from B&M Pond, one sample from Content Brook, and one sample from the West Middlesex Canal. Only one phenanthrene exceedance occurred, within a sample collected from B&M Pond.

7.2 Further Analysis

The Work Plan for the OU-4 RI/FS Addendum includes a step for reviewing the sediment toxicity testing and chemistry data to determine if additional stored sediment samples, collected during the 2004 field event, require full characterization (i.e., toxicity and chemical analysis). Based on the toxicity test results presented in this report, sediment toxicity of greater than 30% inhibition of survival for *H. azteca* and greater than 30% inhibition of growth of *C. tenans* was observed at sampling location SED-18. Lesser degrees of toxicity, with smaller reductions of growth of *C. tenans*, were observed at sampling locations SED-05 and SED-11. The Statement of Work for the OU-4 RI/FS stated that, "If toxicity is found, then an attempt will be made to identify risk-based cleanup concentrations based on regression analysis of contaminant concentration versus toxicity from these four sediment samples". Further discussions with EPA are recommended to determine whether significant toxicity has been demonstrated at site locations and whether additional sediment samples should be analyzed for toxicity and chemistry, should PRGs need to be established based on the results of the sediment toxicity tests.

**Table 2-1. Sediment Sample Location Rationale
Iron Horse Park Superfund Site - OU-4**

Area	Sample ID	Historical Sampling Location	Rationale/Relative Contaminant Concentrations⁽¹⁾
Content Brook	SED-01	SD-030	Maximum silver and arsenic
	SED-02	SD-310	Maximum aluminum; intermediate DDD
	SED-03	SD-102	Slightly lower levels of metals; intermediate DDD
	SED-04	SD-117	Lower levels of metals than SD-102
B&M Pond	SED-05	SD-304	Maximum chromium, zinc, and DDD
	SED-06	SD-107	low DDD; less than half concentrations of metals in SD-304
	SED-07	New location	Sample in pond toward NW corner
	SED-08	New location	Berm breach between SD-016 and SD-303
W. Middlesex Canal	SED-09	SD-029	Maximum vanadium and cobalt
	SED-10	SD-028	Maximum manganese
	SED-11	SD-308	higher PAHs than SD-029/028; variable metals
	SED-12	SD-026	intermediate DDD; variable metals
Richardson Pond	SED-13	SD-111	Maximum barium; intermediate DDD
	SED-14	New location	Near SD-111, but in open water
	SED-15	SD-309	Intermediate metals; intermediate PAHs
	SED-16	SD-314	low PAHs, low metals
Unnamed Brook	SED-17	SD-317	Maximum lead and copper
	SED-18	SD-013	High metals
	SED-19	SD-010	High PAHs; lower metals than SD-013; intermediate DDD
	SED-20	SD-118	Maximum PAHs
Round Pond	SED-21	reference	wetland area at end of John E. Smith Drive
	SED-22	reference	backwater area at end of John E. Smith Drive
	SED-23	reference	open water sample in pond

Table 2-2. Summary of Sediment Sample Descriptions ⁽¹⁾
Iron Horse Park Superfund Site - OU-4

Area	Sample Location	Habitat ⁽²⁾	Water Depth (ft)	Color ⁽³⁾	Sample Description	Comments
Content Brook Area	SED-01	Brook	0.1	Dark Brown	silt & v. fine sand, some sand, iron staining, sheen on sediment near location	hydrocarbon odor
	SED-02	Wetland	0.33	V. Dark Grayish Brown	silt, with some organics (mostly phragmites & roots)	gray, turbid water, hydrocarbon odor
	SED-03	Brook	2	V. Dark Brown	silt & fine sand, some sand and leaves	brown, stained water
	SED-04	Brook	2-3	V. Dark Gray	silt & fine sand, some leaves and twigs	sulfide odor, submerged vegetation
B&M Pond Area	SED-05	Open Water	3	Black	silt & v. fine sand, some roots and twigs	hydrocarbon/sulfide odors, sheens on water surface
	SED-06	Open Water	2.7	V. Dark Grayish Brown	sand, fine sand & silt, some gravel, twigs, acorns	high degree of staining, dense submerged vegetation
	SED-07	Open Water	2.5	Black	silt & v. fine sand, some roots, twigs	stained water with some sheens
	SED-08	Wetland / Canal	2.5	Black	silt & fine sand, little coarse sand, leaves, twigs	brown, stained water with some sheens and algal cover
West Middlesex Canal	SED-09	Canal	2	V. Dark Grayish Brown	silt & v. fine sand with some fine sand, twigs	stained water with biological sheens when sediment disturbed, hydrocarbon odor
	SED-10	Canal	2.4	V. Dark Grayish Brown	silt and v. fine sand with some sand, coarse sand, leaves, twigs	stained water with some sheens, submerged vegetation
	SED-11	Canal	2.5-3.5	V. Dark Brown	silt, fine & coarse sand, some sticks	duck weed at surface, submerged vegetation
	SED-12	Canal	0.8	Black	silt & fine sand, some v. fine sand, little coarse sand, leaves, twigs	stained water with some sheens, hydrocarbon odor in sediment
Richardson Pond	SED-13	Wetland	0.25	V. Dark Gray	silt, little fine & coarse sand, roots	murky, stained water with some sheens
	SED-14	Wetland	1.33	V. Dark Grayish Brown	silt, little fine sand, phragmite roots	slight staining, 2 feet visibility
	SED-15	Wetland	0.05	V. Dark Brown	silt, some fine & coarse sand, organics	stained water, some biological sheen
	SED-16	Open Water	2.5	Not Recorded	silt & v. fine sand, little fine sand, organics	slight stained water, 2-3 feet visibility

**Table 2-2. Summary of Sediment Sample Descriptions ⁽¹⁾
Iron Horse Park Superfund Site - OU-4**

Area	Sample Location	Habitat ⁽²⁾	Water Depth (ft)	Color ⁽³⁾	Sample Description	Comments
Unnamed Brook	SED-17	Channel / Brook	1	Black	silt, little coarse sand, leaves, fragments of cement	sheen on water & in sediment sample
	SED-18	Channel / Brook	2.5	Very Dark Gray	silt & fine sand, some fine and coarse sand	little staining, biological sheens
	SED-19	Channel / Brook	1.5	Very Dark Gray	fine & coarse sand, some silt	upstream of outfall, hydrocarbon odor, some sheens
	SED-20	Channel / Brook	0.5 - 1	Black	silt & v. fine silt, little coarse sand, twigs	very turbid, stained water with sheens
Reference Area - Round Pond	SED-21	Open Water	1.7	Black	high organic fraction with roots, leaves, twigs with some silt and fine sand	sulfide odor in sediment, stained water
	SED-22	Open Water	2.2	Very Dark Brown	high organic fraction with roots, leaves, with some silt and fine sand	slightly stained water
	SED-23	Open Water	4.6	Black	silt & v. fine sand, some twigs	stained water with heavy vegetation

⁽¹⁾ Further detail can be found on the sediment sampling field data sheets in Appendix C.

⁽²⁾ Habitats include wetland, open water (sample collected at edge of open water), channel, or canal

⁽³⁾ Color as determined with the Munsell Color Chart. See field data sheets in Appendix C for Munsell classification

**Table 2-3. Summary of Surface Water Sampling Field Parameters
Iron Horse Park Superfund Site - OU-4**

Water Body	Sample Location ID ⁽¹⁾	Temperature (°C)	pH	Dissolved Oxygen (mg/L)	Specific Conductivity (µS/cm)	Oxidation Reduction Potential (mV)	Turbidity (NTU)
B&M Pond	SW-BM	15.36	6.08	3.04	211	53.5	3.51
Richardson Pond	SW-RP	16.53	6.53	1.35	378	298	1.64
West Middlesex Canal	SW-MC	17.98	6.48	2.51	129	NM	NM

⁽¹⁾ Dry weight corrected result

⁽²⁾ For metals, detected results are shown as recorded result ± standard deviation for each metal

E - Estimated value; exceeds upper limit of calibration

**Table 6-2. Rationale for Selection of Sediment Samples for Full Characterization
Iron Horse Park Superfund Site - OU-4**

Area	Sample Location	Selected for Full Characterization? ⁽¹⁾		Rationale for Selection
		Yes	No	
Content Brook Area	SED-01	X		Maximum arsenic detection
	SED-02		X	
	SED-03		X	
	SED-04		X	
B&M Pond	SED-05	X		Maximum historical DDD detection, high Microtox toxicity, Cu, Pb, and PAHs
	SED-06		X	
	SED-07		X	
	SED-08		X	
West Middlesex Canal	SED-09		X	Highest historical PCB detections, high Microtox toxicity and Pb
	SED-10		X	
	SED-11	X		
	SED-12		X	
Richardson Pond	SED-13		X	
	SED-14		X	
	SED-15		X	
	SED-16		X	
Unnamed Brook	SED-17		X	High PAHs, low metals and Microtox toxicity (Microtox assay is not very sensitive to PAHs)
	SED-18	X		
	SED-19		X	
	SED-20		X	
Reference Area - Round Pond	SED-21		X	No detectable Microtox toxicity (lower Pb than SED-21, lower Microtox results than SED-23)
	SED-22	X		
	SED-23		X	

⁽¹⁾ All sampling locations underwent screening analyses (including Microtox® testing, XRF screening for target metals, and PAH and PCB immunoassay test kits). Full characterization includes toxicity testing, grain size analyses, and chemical analyses for 4,4'-DDD/PCBs, PAHs, target metals, and TOC)

**Table 6-3. Summary of Sediment Characteristics
Iron Horse Park Superfund Site - OU-4**

Area	Sample Location	Habitat	Water Depth (ft)	% Solids	Grain Size Description	Notes from Grain Size Analysis
Content Brook Area	SED-01	Brook	0.1	33.2	82.3% Sand; 15.9% Silt&Clay; 1.8% Gravel	Very high organic content; wet, very dark brown silty sand
B&M Pond Area	SED-05	Open Water	3	11.2	87.2% Sand; 8.4% Silt&Clay; 4.4% Gravel	Very high organic content; wet, very dark brown sand with silt; smell of petroleum
West Middlesex Canal	SED-11	Canal	2.5-3.5	28.1	79.1% Sand; 16.6% Gravel; 4.3% Silt&Clay	Wet, black sand with gravel and organics
Unnamed Brook	SED-18	Channel / Brook	2.5	33.9	69.6% Sand; 28.4% Silt&Clay; 2.0% Gravel	High organic content; wet, very dark brown silty sand
Reference Area - Round Pond	SED-22	Open Water	2.2	17.5	88.1% Sand; 11.9% Silt&Clay	High organic content; wet, very dark brown sand with silt and organics

Total PAHs⁽¹⁾		1955	173860	92231	627	12416	930

PAL Exceedances are highlighted

⁽¹⁾ Total PAH results are the sum of detected concentrations. Non-detect values were not included, as they were assumed to be zero for this summation

EB - As a qualifier for soil/sediment samples: Analyte is also detected in the equipment blank

FD - Field Duplicate

J - The concentration is an estimated quantity

mg/Kg - milligrams per Kilogram

mg/L - milligrams per Liter

PAL - Project Action Limit

R - The data are rejected as unusable

U - Analyte was analyzed for but not detected

ug/Kg - micrograms per Kilogram

ug/L - micrograms per Liter

UJ - The sample quantitation limit is an estimated quantity

Metal and PAH samples for sediments were freeze dried

PAL Exceedances are highlighted

EB - As a qualifier for soil/sediment samples: Analyte is also detected in the equipment blank

FD - Field Duplicate

J - The concentration is an estimated quantity

mg/Kg - milligrams per Kilogram

mg/L - milligrams per Liter

PAL - Project Action Limit

R - The data are rejected as unusable

U - Analyte was analyzed for but not detected

ug/Kg - micrograms per Kilogram

ug/L - micrograms per Liter

UJ - The sample quantitation limit is an estimated quantity

Percent Lipids	none	2.5	1.8	2.8	2.8	1.5	1.9	5.2	2.1	0.98	0.88	1.6	0.52	7.9

PAL Exceedances are highlighted

⁽¹⁾ Total PAH results are the sum of detected concentrations. Non-detect values were not included, as they were assumed to be zero for this summation

EB - As a qualifier for soil/sediment samples: Analyte is also detected in the equipment blank

FD - Field Duplicate

J - The concentration is an estimated quantity

mg/Kg - milligrams per Kilogram

mg/L - milligrams per Liter

PAL - Project Action Limit

R - The data are rejected as unusable

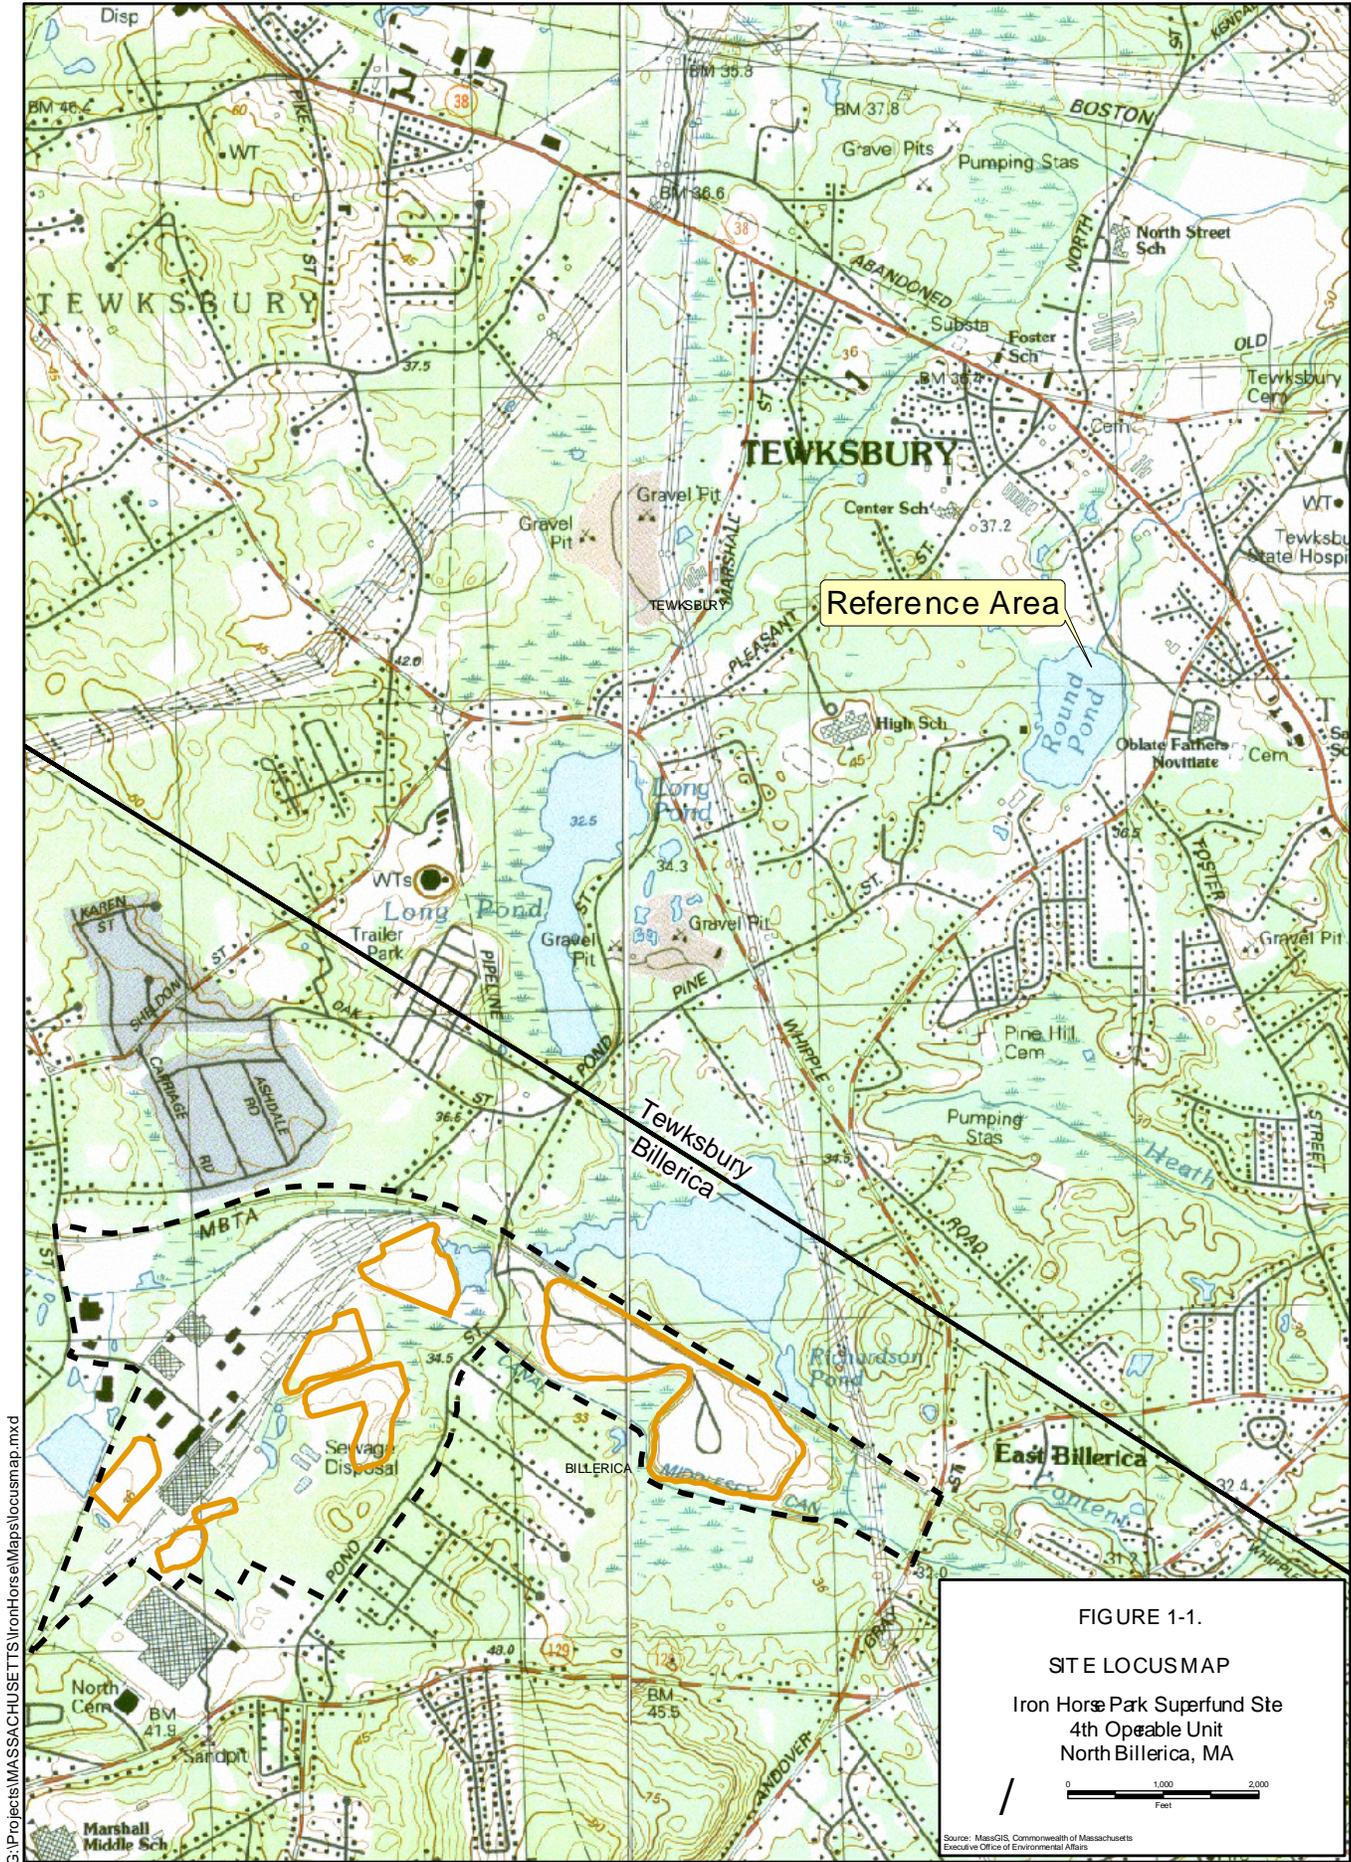

U - Analyte was analyzed for but not detected

ug/Kg - micrograms per Kilogram

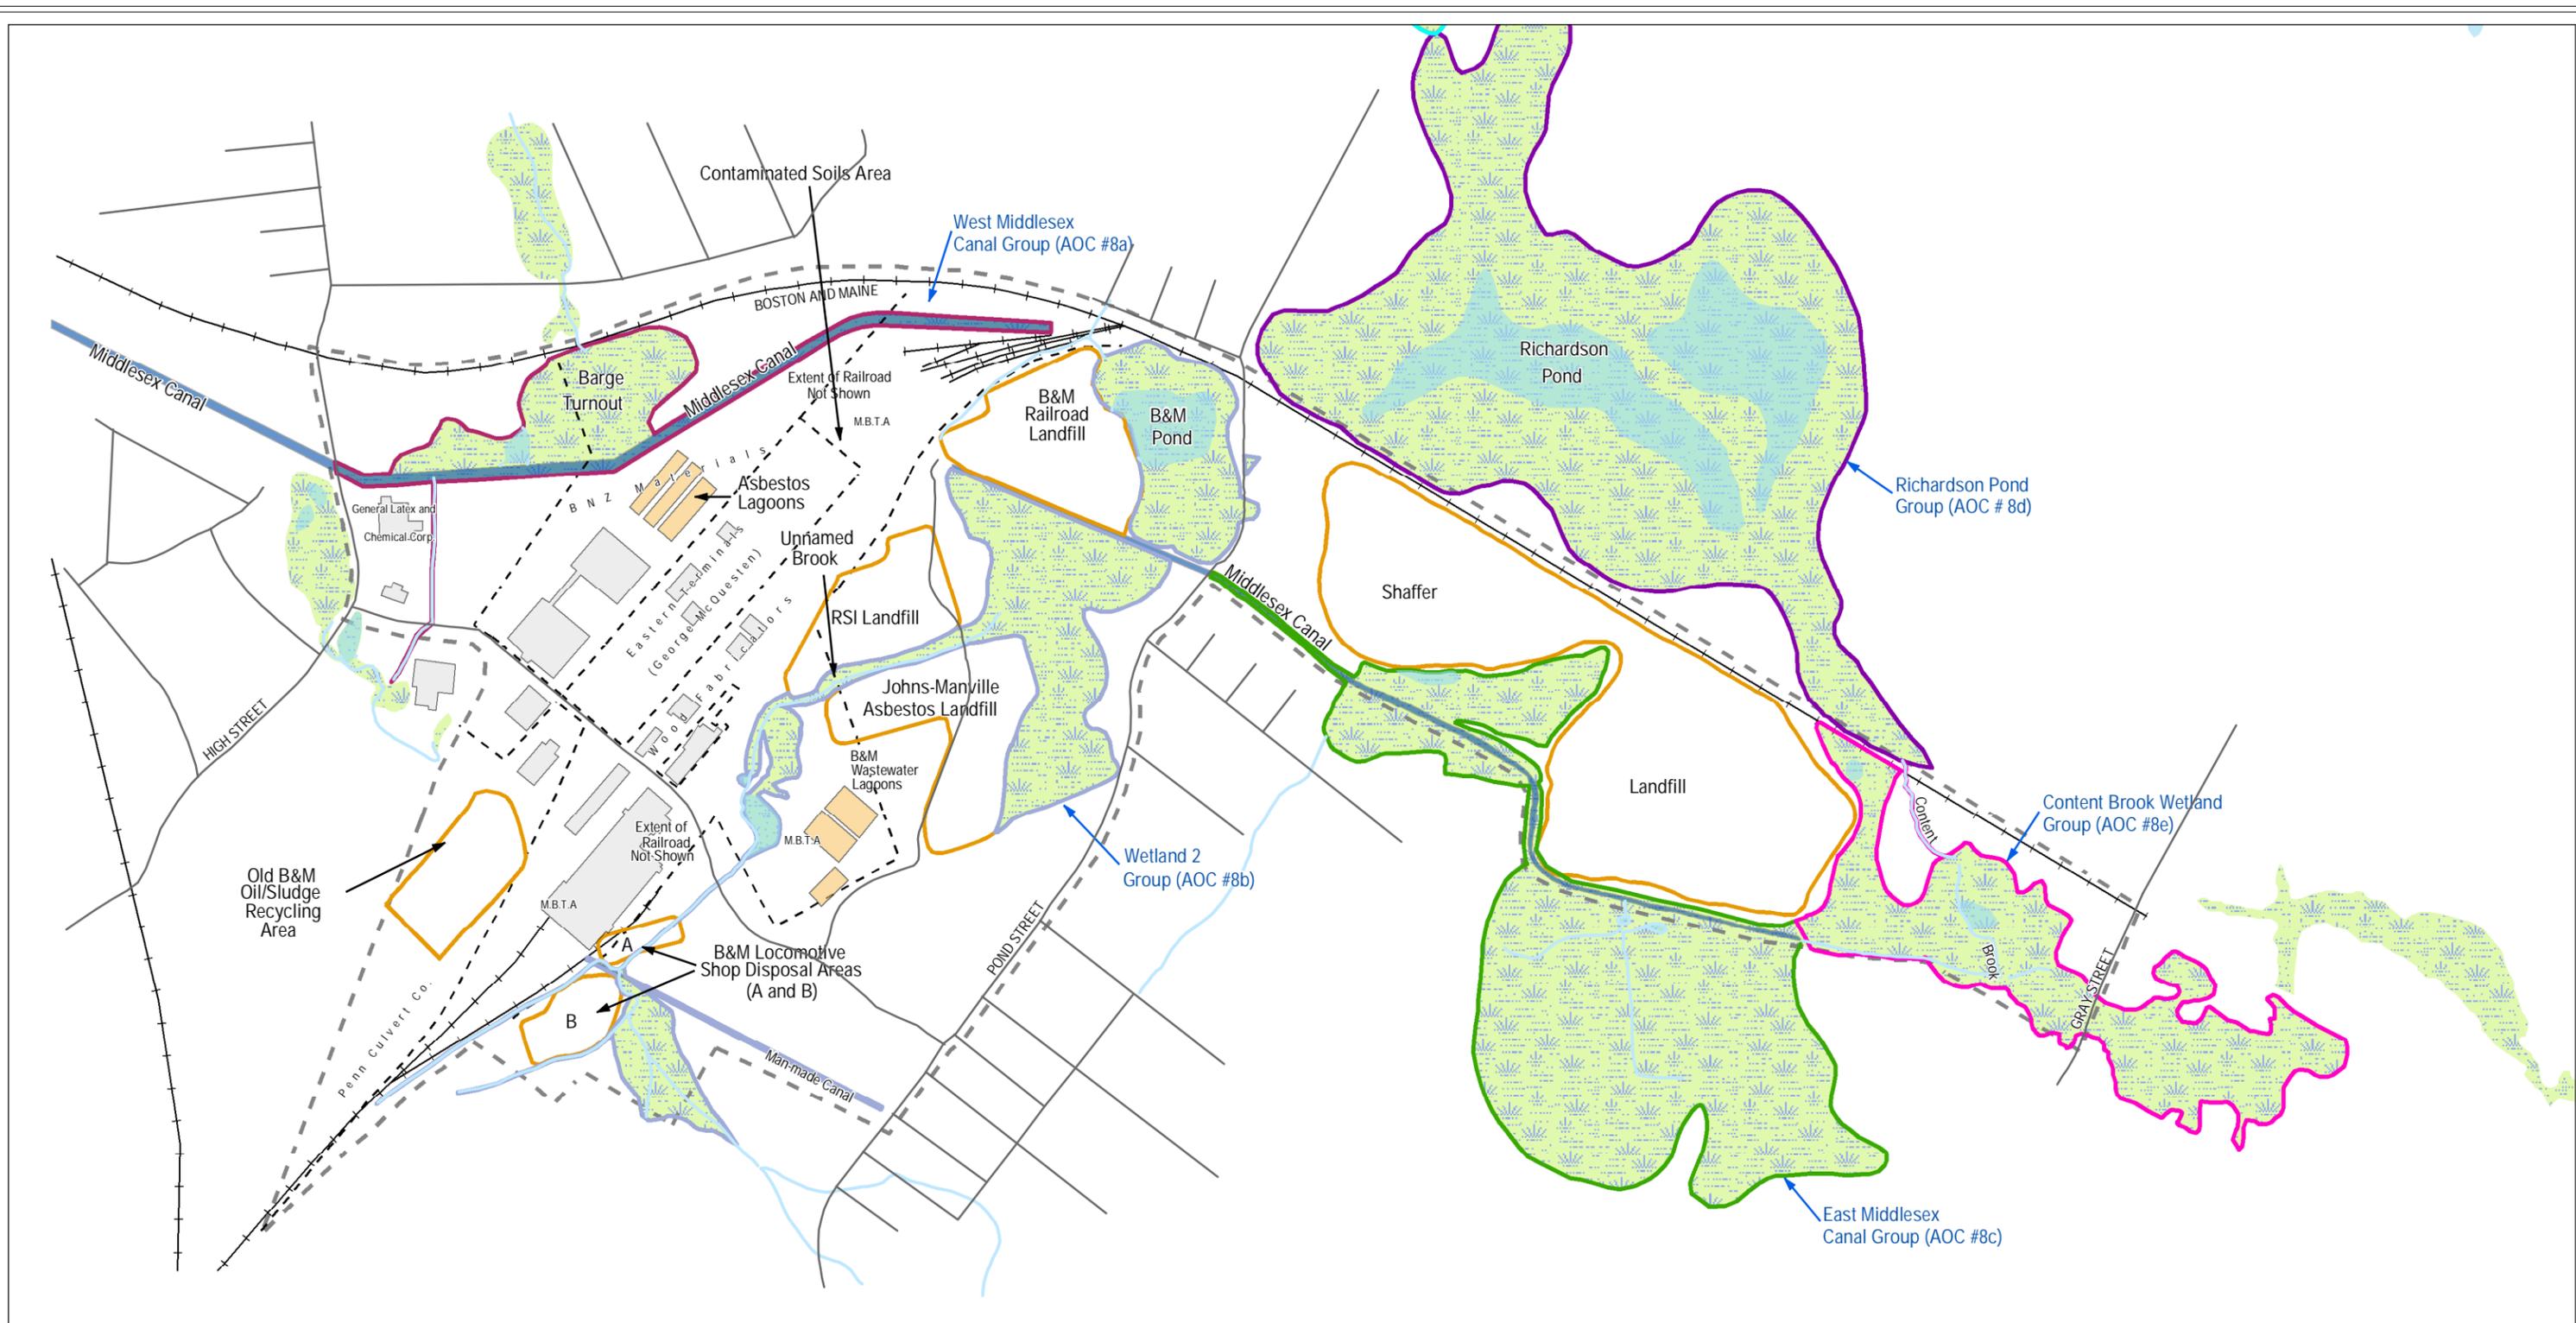

ug/L - micrograms per Liter

UJ - The sample quantitation limit is an estimated quantity

Field Sampling Documentation

SEDIMENT SAMPLING FIELD DATA SHEET

Project Name: Iron Horse Park OU-4 Superfund Site			
Date(s):			
Project #:	036200100.0058.00003	Date:	9/14/04
Sample Location ID:	SED-01	Time:	9:20
Sample #:	DO5199	Weather:	~75° - clear skies, sunny
Samplers:	N. Henderson, P. Dombrowski		
Sample Information:			
Sample Depth:	0-6 in.	Sampling Device:	Eckman Dredge
Water Depth:	1-2 in.		
Distance from Shore:	6-8 in.	GPS Location:	42°34'48.4, 71°14'29.2
Approx. Flow Rate:	0.5 ft/sec		
Field Decon:	<input checked="" type="radio"/> Yes <input type="radio"/> No Dedicated	Sample Type:	<input checked="" type="radio"/> Grab <input type="radio"/> Composite
Munsell Color:	7.5 YR and v. fine sand, some sand		
Sample Description:	7.5 YR 3/2 dark brown		
Other physical characteristics of water body at sample location: (Water color, turbidity, odor, presence of sheens, dead/stressed vegetation)			
Iron staining, sheen on sediment at ^{near} location no odor. Sample collected in small brook. Hydrocarbon odor			
Sample Comments/Description:			
PID reading (after sample homogenization) = 0.0			
Moisture meter reading			
55.5%			

SEDIMENT SAMPLING FIELD DATA SHEET

Project Name: Iron Horse Park OU-4 Superfund Site	
Date(s):	
Project #: 036200100.0058.00003	Date: 9/14/04
Sample Location ID: SED-02	Time: 15:05
Sample #: D05200	Weather: sunny, high 70's clear skies
Samplers: N. Henderson / P. Dombrowski	

Sample Information:

Sample Depth: 0-6 in	Sampling Device: Eckman Dredge
Water Depth: 4 inches	
Distance from Shore: no shore	GPS Location: not measured location is 1/2 way between fence + RR tracks <i>(see below)</i>
Approx. Flow Rate: None	
Field Decon: <input checked="" type="radio"/> Yes <input type="radio"/> No Dedicated	Sample Type: <input checked="" type="radio"/> Grab <input type="radio"/> Composite

Munsell Color: 2.5Y 3/2 very dark grayish brown

Sample Description: silt - some organics - phragmites roots + leaves.

Other physical characteristics of water body at sample location:
(Water color, turbidity, odor, presence of sheens, dead/stressed vegetation)

water turbid - grayish in color
sheen
phragmites everywhere - sample collected in middle of phragmites wetland.
hydrocarbon odor

Sample Comments/Description:

PID reading (after sample homogenization) = 0.0 ppm as isobutylene

Moisture meter reading
70.3 %

GPS location
42° 34' 56.5"
71° 14' 33.9"
went back on 9/23/04 for GPS measurement

SEDIMENT SAMPLING FIELD DATA SHEET

Project Name: Iron Horse Park OU-4 Superfund Site			
Date(s):			
Project #:	036200100.0058.00003	Date:	9/14/04
Sample Location ID:	SED-03	Time:	11:10
Sample #:	DO5201	Weather:	Sunny, high 70's
Samplers:	N. Henderson/p. Dunbrowski		
Sample Information:			
Sample Depth:	0-6 in	Sampling Device:	Eckman Dredge
Water Depth:	2 ft.		
Distance from Shore:	6 ft.	GPS Location:	Same as before (see below)
Approx. Flow Rate:	0 (flow)		
Field Decon:	<input checked="" type="radio"/> Yes <input type="radio"/> No Dedicated	Sample Type:	<input checked="" type="radio"/> Grab <input type="radio"/> Composite
Munsell Color:	10 YR 2/2 very dark brown		
Sample Description:	Silt and fine sand, some sand leaves.		
Other physical characteristics of water body at sample location: (Water color, turbidity, odor, presence of sheens, dead/stressed vegetation)			
A lot of floating pollen. water is stained. visibility is 6 inches. Color - brown			
Sample Comments/Description:			
Neighbor came over at ¹⁰ + asked about us if we were working on the beaver problem. She said that there should be flow here, but beaver dams stop flow. PID reading (after sample homogenization) = 0.0 <u>Moisture meter reading</u> 84.3%			
GPS measurement done during 2nd site visit - 42° 34' 45" 71° 14' 19.2"			

SEDIMENT SAMPLING FIELD DATA SHEET

Project Name: Iron Horse Park OU-4 Superfund Site			
Date(s):			
Project #:	036200100.0058.00003	Date:	9/14/04
Sample Location ID:	SED-04	Time:	1310
Sample #:	DOS202	Weather:	Clear
Samplers:	Henderson, Dambrowski, O'Connor		
Sample Information:			
Sample Depth:	2-4' 2-4'	Sampling Device:	Eckman Dredge
Water Depth:	2-3'	GPS Location:	42° 34' 52.6"
Distance from Shore:	4-10'		71° 14' 25.8"
Approx. Flow Rate:	0	Sample Type:	<input checked="" type="radio"/> Grab <input type="radio"/> Composite
Field Decon:	<input checked="" type="radio"/> Yes <input type="radio"/> No Dedicated	Ekman	
Munsell Color:	2.5Y 3/1 very dark grey		
Sample Description:	Silt and fine sand Some leaves + sticks		
Other physical characteristics of water body at sample location: (Water color, turbidity, odor, presence of sheens, dead/stressed vegetation)			
Duckweed, small sulfur odor bottom hard, many grabsto composite & sample, - water stained - 1' visibility - 11' pads and submerged vegetation along banks - no sheens			
Sample Comments/Description:			
PID reading (after sample homogenization) = 0.0 ppm as isobutylene			
Moisture meter reading 85.8%			
Sample difficult to collect. A lot of downed trees/branches in water.			

SEDIMENT SAMPLING FIELD DATA SHEET

Project Name: Iron Horse Park OU-4 Superfund Site			
Date(s):			
Project #:	036200100.0058.00003	Date:	9/15/04

Sample Location ID:	SED-09	Time:	8:40
Sample #:	D05208	Weather: cloudy, high 60's	
Samplers:	P. Dombrowski + N.		

Henderson

Sample Information:

Sample Depth:	0-6 in.	Sampling Device:	Eckman Dredge
Water Depth:	2 ft.		
Distance from Shore:	5 ft.	GPS Location:	42° 35' 18.9" 71° 15' 31.6"
Approx. Flow Rate:	0		
Field Decon:	<input checked="" type="radio"/> Yes <input type="radio"/> No Dedicated	Sample Type:	<input checked="" type="radio"/> Grab <input type="radio"/> Composite

Munsell Color: 2.5Y 3/2 very dark grayish brown

Sample Description: silt and v. fine sand. some fine sand
sticks

Other physical characteristics of water body at sample location:
(Water color, turbidity, odor, presence of sheens, dead/stressed vegetation)

Stained water
visibility - 1 ft.
no submergent vegetation
a lot of overhanging brush
~~no~~ sheen sheen when sediment disturbed
sed. smells like hydrocarbon

Sample Comments/Description:

sheen on sediment in bowl. + in jars
PID = 2.6 ppm as isobutylene

Moisture meter reading
98.1%

SEDIMENT SAMPLING FIELD DATA SHEET

APPENDIX E

Massachusetts Department of Fisheries and Wildlife Scientific Collection Permit

Division of Fisheries & Wildlife

Wayne F. MacCallum, Director

Scientific Collection Permit

FISH

METCALF & EDDY, INC.
NATHAN HENDERSON
701 EDGEWATER DRIVE
WAKEFIELD, MA 01880

VALID

2004

DATE: 8/19/2004
PERMIT#: 204.04SCF

Subpermittee(s): TONY RODOLAKIS

is (are) hereby authorized, in accordance with the provisions of Section 4, Chapter 131 and 131A of the Massachusetts General Laws, to remove from the wild within the Commonwealth, subject to conditions set forth below, the following species and numbers:

MAY TAKE UP TO A TOTAL 200 FISH OF ANY SPECIES FROM WATER WITHIN AND ADJACENT TO IRON HORSE PARK FOR BASELINE ECOLOGICAL RISK ASSESSMENT.

The following method(s) of taking is (are) hereby authorized:

BACKPACK ELECTROSHOCKING, HOOP NETS, SEINES

Collection activities under this permit shall be restricted to the following locations, subject to the approval of private landowners

IRONHORSE PARK, BILLERICA/TEWKSBURY

All specimens secured under this permit shall be donated to the following Institutions:

RETAINED FOR FLESH ANALYSIS

No specimen taken under the authority of this permit may be sold. No specimens may be transferred to another not duly licensed.

This permit of a copy thereof shall be carried at all times by the permittee and subpermittee(s) while engaged in the activities authorized herein.

This permit does not absolve the permittee from compliance in full with any and all other applicable federal, state and local requirements, including the acquisition of a federal endangered species permit if required.

Upon expiration of this permit, a complete report detailing all collection activities shall be filled with this office and must include a listing of all species taken, numbers of specimens, and the disposition of same.

This permit, unless sooner revoked for cause, shall expire on December 31 of the year of issue.

Handwritten signature of Wayne F. MacCallum in black ink.

APPENDIX F

Data Validation and Data Quality Objectives Evaluation

F.1 DATA VALIDATION

Tier II data validation was performed on all laboratory chemical analytical data associated with the September/October 2004 sampling event with the exception of alkalinity and TOC, which was validated to Tier I. The level of validation required was defined in the site-specific SAP (M&E, 2004b) and was met for all matrices. Non-chemical analyses for grain size and toxicity were not formally validated.

The analytical data was validated in accordance with the following U.S. EPA Region I guidance documents, modified where appropriate: *Region I EPA-New England Data Validation Functional Guidelines for Evaluating Environmental Analyses* (U.S. EPA, 1996), *Region I Laboratory Data Validation Functional Guidelines for Evaluating Inorganics Analysis, February 1989 criteria* (U.S. EPA, 1988) and *Contract Laboratory Program National Functional Guidelines for Inorganic Data Review* (U.S. EPA, 2004). In Tier II data validation a completeness evidence audit is performed to verify the presence of all laboratory data and documentation and the results of all quality control checks and procedures are evaluated and used to assess and qualify the sample results.

F.2 DATA QUALITY OBJECTIVES EVALUATION

To determine if project data quality objectives (DQOs) for this project were met, the sample and quality control results were assessed during Tier II data validation. Data quality was assessed in terms of precision, accuracy and bias, sensitivity, representativeness, completeness, and comparability. For each of these criteria, quality objectives were established prior to the onset of the sampling program and sample and quality control results were evaluated in relation to these quality objectives. To achieve the project DQOs and for data to be deemed usable, these established quality objectives must be met. The assessment of the sample data precision, accuracy and bias, sensitivity, representativeness, completeness, comparability, and the usability of the data, as a result of this assessment, is discussed in detail below.

F.2.1 Precision

Precision is defined as the degree to which two or more measurements are in agreement. Field precision was measured by comparing sample results of field duplicate samples and analytical precision was measured by comparing sample results of matrix spike/matrix spike duplicate (MS/MSD) sample results for organic parameters and laboratory replicate samples for inorganic parameters, as well as dual column precision for DDD/PCBs analyses. The relative percent difference (RPD) between duplicate results was calculated and then compared to quality control acceptance criteria.

F.2.1.1 Field Precision. Field duplicates were collected by taking two aliquots of the same sample and submitting them to the laboratory for analysis as two separate samples (duplicate subsamples). Field duplicate samples were collected at a frequency of at least one for every 20 samples per matrix per parameter for use in assessing field precision. The actual number of field duplicates collected are specified in Table F-1. Field duplicates for sediment and surface water samples were collected at the required frequency for all parameters (fish field duplicate samples

were not required).

Field duplicate precision was assessed by comparing the calculated relative percent differences (RPDs) to the quality control acceptance criteria specified in the data validation guidelines. If the sample results were near or below the quantitation limit (QL), the RPD was not calculated and the sample results were considered to meet precision acceptance criteria and were not qualified. When the RPD acceptance criteria were exceeded, the results for those compounds in the associated samples were considered to be estimated values. Sample heterogeneity is one possible cause.

Sediment. For PAHs, 17 of 25 results were qualified as estimated due to high field duplicate RPD. In all instances, the concentration of the target analyte was higher in the parent field sample than its field duplicate, with the RPD exceedance ranging from 51 to 79%. The sample location selected for field duplicate analysis had PAH concentrations an order of magnitude higher than any other location, and may be subject to more heterogeneity than other locations.

Field duplicates met RPD acceptance criteria for the DDD/PCBs analysis.

For metals, two target analytes (manganese and vanadium) had poor field duplicate precision.

Surface Water. The field duplicate results met RPD acceptance criteria.

Fish. No field duplicates were collected for fish analysis.

Precision as measured by field duplicate evaluation was within project quality objectives for 32% of the PAH sediment data, 100% of the DDD/PCBs sediment data, 82% of the metals sediment data, and 100% of the surface water metals data. Overall, the field duplicate assessment indicated acceptable field precision for all matrices, with the exception of sediment PAHs, for the September/October 2004 sampling event.

F.2.1.2 Analytical Precision. Matrix spike and matrix spike duplicate samples for the PAH and DDD/PCBs analyses and matrix spike and laboratory replicate samples for the inorganic analyses were performed at a frequency of one per sample preparation batch, as stated in the DAS analytical specifications. Dual column precision was evaluated for every sample for DDD/PCBs analysis.

The method precision objectives, in terms of duplicate sample RPDs, were assessed using the criteria summarized in the DAS analytical specifications. For MS/MSD and replicate assessment, if the acceptance criteria were not met for the organic analyses analytical precision checks, only the associated results in the investigative sample were qualified as estimated. If the acceptance criteria were not met for the inorganic analyses precision checks, the associated results for all samples in the sample batch were qualified as estimated. If the analyte levels in the investigative sample were higher than the spike concentrations, the duplicate analysis was not evaluated since initially high concentrations of the analytes can preclude the quantitation of the spike amounts added.

Sediments. For PAHs, all 25 target analytes were qualified as estimated due to poor MS/MSD precision. Recoveries were consistently low, and the MSD was consistently lower than the MS sample. A possible cause of this imprecision may be sample heterogeneity, as sample concentrations, as measured in the unspiked sample, are subtracted from the spiked sample result prior to calculating recovery and RPD.

All MS/MSD results met acceptance criteria for DDD/PCBs analysis.

For metals, one analyte (silver) was qualified as estimated in all samples due to poor laboratory duplicate precision.

Surface Water. All laboratory duplicate precision criteria were met.

Fish. All MS/MSD RPD criteria were met for the PAH analysis.

For metals, four analytes (barium, chromium, cobalt, and manganese) were qualified as estimated due to poor laboratory duplicate precision.

Precision as measured by MS/MSD and laboratory duplicate evaluation was within the project quality objectives for none of the sediment PAH data, 100% of the DDD/PCBs sediment data, 91% of the sediment metals data, 100% of the surface water data, 100% of the fish PAH data, and 64% of the fish metals data.

Overall, the MS/MSD and laboratory duplicate assessment indicated acceptable precision for all matrices, with the exception of sediment PAHs, for the September/October 2004 sampling event.

Dual column precision for pesticide analyses was assessed by evaluating the percent difference (%D) between column results for each compound for each sample. Sample results were considered estimated or unusable according to the dual column precision nonconformances. When possible, results that would have been rejected due to poor dual column precision were reported from a less dilute analysis for which the result was above the calibration range (requiring it to be qualified as estimated) but for which dual column precision was within acceptance criteria.

For dual column precision, one DDD result was rejected and four Aroclor 1260 results were estimated in sediment samples due to poor dual column precision. Precision as measured by dual column percent difference was within the project quality objectives for 90% of the DDD/PCBs data.

F.2.2 Accuracy and Bias

Accuracy is defined as the degree to which the detected value represents the true value. Accuracy in the field was assessed through the collection and analysis of equipment blanks for PAHs, DDD/PCBs, and metals analyses for sediment samples; and metals analyses for surface water samples. Analytical accuracy in the laboratory was assessed through the evaluation of cooler temperatures, sample preservation and holding times, laboratory method blanks, surrogate spike recoveries, MS/MSD recoveries, laboratory fortified blanks, laboratory control spikes, and

performance evaluation (PE) samples. The field and analytical accuracy assessment is described below.

F.2.2.1 Field Accuracy. Accuracy in the field was assessed through the collection and analysis of equipment blanks for PAHs, DDD/PCBs, and metals analyses.

Equipment Blanks

Equipment blanks were used to evaluate the potential contamination of samples from the sampling equipment, sample containers, and sample handling and collection procedures. To collect the equipment blanks, deionized water was run over or through sample collection equipment after the initial decontamination procedure and prior to use. One equipment blank was collected for each matrix per parameter. Equipment blanks were not required for TOC/TCO, alkalinity, grain size, or toxicity samples due to the nature of the analysis. The scheduled frequency for the collection of equipment blanks was met or exceeded for all matrices and parameters during the sampling event.

Equipment blank results were evaluated to determine if contaminants were detected and the quantity of samples affected. Since an aqueous equipment blank cannot be directly applied to qualify results for solid matrices, sediment results were qualified with an “EB” flag for those compounds detected in the associated equipment blank. The “EB” qualifier indicates an indeterminate amount of sampling error has potentially affected the sample results.

Sediments. Seven target PAHs were detected in the equipment blank, with 42 associated results qualified with an “EB” to indicate that an indeterminate amount of the concentration may be attributable to contamination from equipment for these compounds. Note: Nondetect PAH results in the equipment blank were rejected due to a gross exceedence of holding time.

No target analytes were detected in the equipment blank associated with DDD/PCBs analysis.

For metals analysis three target analytes (barium, manganese, and zinc) were detected in the equipment blank resulting in 18 associated sample results qualified with an “EB” to indicate that an indeterminate amount of the concentration may be attributable to contamination from equipment for these analytes.

Surface Water. No data required qualification due to equipment blank contamination.

Fish. No equipment blank was associated with the fish samples.

Accuracy and bias as measured by equipment blank evaluation against project quality objectives for the sediment PAHs could not be evaluated due to the rejection of nondetect results in the equipment blank. Therefore, 28% of the sediment PAH data did not meet project quality objectives. Accuracy and bias as measured by equipment blank evaluation against project quality objectives for the sediment metals and surface water metals was 73% and 100%, respectively. Although it cannot be quantified, the potential of contamination from the equipment blank causing a false positive is reduced as the reported sample concentration increases. For example, it is

prudent to assume that any equipment contamination is negligible for the highest reported concentration of phenathrene (13,000 µg/kg) compared to a possible impact on the lowest reported concentration (29 µg/Kg) in the sediment samples.

F.2.2.2 Analytical Accuracy. Analytical accuracy in the laboratory was assessed through the evaluation of sample preservation and holding times, laboratory blanks, surrogate spike recoveries, MS/MSD recoveries, laboratory control sample recoveries, and performance evaluation (PE) samples.

Sample Preservation and Holding Times

In order to obtain accurate sample results, the samples must be properly cooled and chemically preserved prior to analysis and analyzed/prepared within the technical holding time specified in the analytical method. Shipment cooler temperatures were evaluated upon receipt at the laboratory for all samples. All cooler temperatures for this sampling event were received within the required range, with the exception of coolers received by the lab with sediment metals samples from their freeze drying subcontractor. No validation actions were taken as the metals results would not be expected to be adversely affected by the temperature exceedences that were noted. Sample pH was measured by the laboratory for the surface water samples and equipment blanks submitted for metals analysis to verify sample preservation in the field. The data usability was not affected by thermal and chemical preservation.

Technical holding times were assessed for each parameter. If the holding time was exceeded, positive and nondetect results were qualified as estimated, biased low, for all results for that sample. If the holding time exceeded double the method requirement, positive results were qualified as estimated, biased low, and nondetect results were rejected to eliminate false negatives caused by sample degradation.

All sediment PAH results were qualified as estimated due to holding time exceedences. In addition, nondetect PAH results for thte sediment equipment blank was rejected due to holding time exceedences more than double the method requirement.

Analytical accuracy and bias as measured by holding time evaluation were within project objectives for none of the PAH sediment samples. Holding times were not exceeded for the sediment DDD/PCBs and metals analyses, surface water analyses, and fish analyses. Overall data usability was not affected by holding time exceedences.

Laboratory Blanks

Laboratory blanks were used to evaluate the potential contamination of samples from the preparation and analytical procedures. Laboratory blanks were prepared and/or analyzed along with each batch of field samples, at a frequency of one per 20 samples per matrix per parameter per day of digestion/extraction and/or analysis. The scheduled frequency for the analysis of laboratory blanks was met or exceeded for all matrices and parameters. Laboratory blanks were evaluated against their associated field samples to determine if a laboratory condition contributed to false positives or high bias in the field samples. Select sample results were negated on the basis

of this comparison, in accordance with the data validation guidelines.

Sediments. For PAH analyses, nine target analytes were detected in the method blank, but only one sample result required qualification as nondetect as other results were either nondetect or greater than the blank action level.

No blank qualification of data was necessary for the sediment DDD/PCBs or metals analysis.

Surface Water. No blank qualification of surface water data was required.

Fish. PAH results were affected by low levels of PAHs in laboratory blanks. Data were blank qualified for fifteen target analytes. A total of 84 results were qualified as nondetect at the detection limit and 110 results were qualified as nondetect at the reported concentration. Blank action levels for qualifying data ranged up to ten times the quantitation limit.

Laboratory blank contamination required qualification of 18 results in 13 samples for two target analytes (aluminum and cobalt). Cobalt results were estimated and aluminum results were qualified as nondetect at the reported concentration. The maximum concentration of aluminum data qualified was 2.1 µg/L, compared to a method quantitation limit of 1.0 µg/L.

Accuracy and bias as measured by laboratory blank evaluation was within project quality objectives for 99% of the sediment PAH data, 100% of the sediment DDD/PCBs and metals data, 100% of the surface water data, 69% of the fish PAH data, and 93% of the fish metals data.

Surrogate Spike Recoveries

Surrogate compounds were added to each sample undergoing organic analyses to assess method performance and/or extraction efficiency. Surrogate recoveries were evaluated using acceptance criteria specified in the analytical methods; sample results associated with high surrogate recoveries were considered estimated values with a high bias and results associated with low surrogate recoveries were considered estimated values with a low bias. In general, the samples in each matrix yielded acceptable surrogate spike performances.

Sediment. Three samples had positive PAH results qualified due to low surrogate recovery. For DDD/PCBs analysis four DDD results and two PCB results were qualified as estimated due to high surrogate recovery.

Surface Water. No analyses requiring surrogates was performed on surface water samples.

Fish. All fish PAH analyses met surrogate recovery criteria.

Accuracy and bias as measured by surrogate recovery evaluation was within project quality objectives for 50% of sediment PAH results, 88% of sediment DDD/PCBs results, and 100% of fish PAH results.

MS/MSD Recoveries

Matrix spike compounds were added to select samples prior to preparation and/or analysis to assess the effect of sample matrix on the method performance. The recoveries of the MS compounds were evaluated and compared to acceptance criteria to determine if there was a matrix effect which would affect sample analysis.

Matrix spike analyses were scheduled to be performed at a frequency of one per 20 samples per matrix per parameter, except for fish tissue, which had one per 25 samples, in accordance with the site-specific SAP (M&E, 2004b). The scheduled frequency was met for all samples analyzed for this sampling event.

Matrix spike recoveries were evaluated to assess if matrix effects contributed to a high or low bias in the sample results. In accordance with the data validation guidelines, for organic parameters only, the results of the sample submitted for MS/MSD analysis were qualified if the spike recoveries were outside of the method-specified acceptance criteria. For inorganic parameters, results for all associated samples were qualified if matrix spike or post-digestion spike recoveries were outside of criteria. For organic and inorganic parameters, extremely low recoveries indicated a lack of confidence in associated nondetect results and results for spike compounds that recovered very low were rejected.

Sediments. All 25 target PAHs were qualified as estimated in the sample used for MS/MSD analysis due to low MS and MSD recovery. Recoveries were consistently low, and the MSD was consistently lower than the MS sample. A possible cause of this imprecision may be sample heterogeneity, as sample concentrations, as measured in the unspiked sample, are subtracted from the spiked sample result prior to calculating recovery.

All MS/MSD criteria were met for the DDD/PCBs analysis.

For metals one target analyte (lead) had low MS recovery, resulting in the qualification of all sample results for this analyte.

Surface Water. All MS recovery criteria were met.

Fish. All MS/MSD recovery criteria were met in the PAH analysis. Two metals analytes (cobalt and lead) had MS recoveries outside of acceptance windows that resulted in all results for these analytes being qualified as estimated.

Accuracy and bias as measured by MS and MSD recovery evaluation was within project quality objectives for none of the sediment PAH results, 100% of sediment DDD/PCBs results, 91% of sediment metals results, 100% of fish PAH results, and 82% of fish metals results.

PE Samples. PE samples served as a single-blind check on the laboratory's accuracy. PE samples were scheduled to be submitted to the laboratory at a frequency of one per SDG per matrix per parameter, with the exception of alkalinity, TOC, grain size, and toxicity, for which no PE samples were submitted to the laboratory. The required PE sample frequency was met for all parameters.

Sediments. For PAHs one target analyte (naphthalene) was evaluated as “Action Low” in U.S. EPA’s evaluation of the PE sample results. This evaluation requires rejection of nondetects for this analyte, but since all samples had detections no validation action was required. Both the metals and DDD/PCBs had acceptable results for the PE samples.

Surface Water. All PE samples had acceptable results.

Fish. For PAH analysis 128 results for ten analytes were qualified as estimated due to PE recoveries outside of acceptance windows. All metals PE results met criteria.

Accuracy and bias as measured by PE sample evaluation was within project quality objectives for 100% of sediment PAH, DDD/PCBs, and metals results, 100% of surface water and fish metals results, and 80% of fish PAH results.

F.2.3 Sensitivity

Sensitivity was assessed by the evaluation of analytical quantitation limits (QLs) and the recoveries of target analytes in laboratory fortified blanks (LFBs). Analytical methods were selected such that QLs would allow comparison to the program action limits (PALs) and to historical data. It should be noted that the QLs for PAH analysis were higher than those in the DAS specification, and were based on discussions between M&E and the laboratory prior to commencement of the sampling program, and these revised QLs were incorporated into the site-specific SAP (M&E, 2004b). The revised QLs still were appropriate for comparison to PALs. It should be noted the QLs should be considered target values only, as actual QLs were affected by sample dilutions. Several samples required dilutions due to high concentrations of target analytes. For the most part, QLs were not affected by these dilutions since the results of the undiluted and diluted analyses were combined during the validation in order to report the lowest possible QLs and all results within the calibration range.

An LFB is a reagent blank spiked with all target compounds at or below the QL. The LFB data were used to assess laboratory sensitivity and bias for specific compounds at the QL within an analytical method on a specific instrument and column at the time of sample preparation and analysis. Sensitivity objectives for the LFBs were listed in the DAS specifications for each method in terms of percent recovery. The LFBs were scheduled to be analyzed at a frequency of once per 20 samples per matrix per parameter, except for fish tissue, which had one per 25 samples, in accordance with the site-specific SAP (M&E, 2004b).

The QLs were evaluated for each matrix and parameter to verify that the limits were at or below the QLs required in the associated DAS analytical specification (and discussions with the lab for PAH analyses).

The LFB recoveries were evaluated for each parameter for each matrix to determine if percent recoveries of the spiked analytes were within acceptance criteria. For those compounds with LFB percent recoveries outside of acceptance criteria, associated results were considered estimated. Extremely low recoveries indicated the possibility of false negatives due to poor instrument sensitivity, and associated nondetect results were rejected.

Sediment. For PAH results, one target analyte (dibenzofuran) had a high LFB recovery that exceeded the acceptance window resulting in the qualification as estimated of all results for this analyte.

All LFB criteria were met for the DDD/PCBs and metals analyses.

Surface Water. All LFB criteria were met.

Fish. High PAH LFB recoveries were noted for 20 of 25 target analytes, resulting in the qualification of 229 results. It is reasonable to assume that the low level laboratory blank contamination adversely affected the calculation of LFB recoveries, as no blank correction is performed when calculating the recovery. For metals, two nondetect results for one analyte (vanadium) were rejected due to low LFB recovery. The LFB recovery outside acceptance criteria for four analytes (chromium, copper, vanadium, and zinc) also resulted in the qualification as estimated 98 metals results.

Sensitivity as measured by LFB evaluation was within project quality objectives for 96% of sediment PAH results, 100% for sediment DDD/PCBs and metals results, 100% of surface water metals results, 63% of fish PAH results, and 64% of fish PAH results.

F.2.4 Completeness

Completeness is defined as the measure of the amount of valid data obtained from a measurement system compared to the amount that was expected. For this site, completeness was assessed by comparing: 1) the number of samples successfully analyzed to the number submitted, and; 2) the number of valid measurements to the number of measurements obtained. Completeness was calculated according to the following equations:

1. % completeness = [(number of samples analyzed)/(number of samples submitted)] x 100
2. % completeness = [(number of usable results)/(number of expected results)] x 100

Completeness was evaluated for each matrix and for all samples. The goal for completeness was 90%.

All samples submitted for laboratory analysis were successfully analyzed and 100% completeness was established in these terms for the sampling event.

Sediment. Not including results for the equipment blank, all sediment results were valid and usable, resulting in 100% completeness for that parameter. If equipment blank results are also included in the completeness assessment, 90% completeness was achieved.

The DDD/PCBs analyses achieved 98% completeness and the metals analyses achieved 100% completeness.

Surface Water. 100% completeness was achieved for surface water analyses.

Fish. 100% completeness was achieved for PAH analyses, and 99% completeness was achieved for metals analyses.

Overall, for all matrices a completeness of 99.8% was achieved.

F.2.5 Representativeness

Representativeness expresses the degree to which the data accurately and precisely represent a characteristic of a population, parameter variations at a sampling point, a process condition, or an environmental condition within a defined spatial and/or temporal boundary. Representativeness is a qualitative parameter that is dependent upon the proper design of the sampling program and the laboratory quality control program.

Representativeness in the field was dependent upon the proper design of the sampling program and was satisfied during this sampling event by following the project SAP (M&E, 2004b) and using proper sampling, sample handling, and sample preservation techniques.

Representativeness in the laboratory was provided by using the proper analytical procedures, appropriate methods, and meeting sample holding times. The data are of sufficient quantity and quality to represent the site conditions accurately and precisely and be used to meet project DQOs.

F.2.6 Comparability

Comparability expresses the confidence with which one data set can be compared to another. In order to meet DQOs, data from this sampling event needed to be comparable to each other, to program action levels, and to historical data.

Comparability in the field was dependent upon the proper design of the sampling program and was satisfied by providing that the sampling program was followed and sampling techniques were consistent and correct. Sampling techniques and procedures were kept consistent throughout the September/October 2004 event.

Comparability of laboratory results was dependent on the consistent use of comparable EPA-approved DAS analytical methods, the reporting of data in standardized units, and acceptable PE sample results. The data from this sampling event met these comparability criteria.

F.3 SUMMARY

In general, the data collected during this sampling event met the established quality objectives and

can be considered valid for project DQOs and decision-making purposes. However, 31% of the PAH results in tissue samples were blank qualified due to laboratory issues. The affected positive results for target PAH compounds in the samples were qualified as nondetects (U) at the reported values for those results greater than the quantitation limit or as nondetects (U) at the quantitation limit for those samples concentrations below the quantitation limit due to method blank contamination. The results are usable for project objectives as nondetects at raised detection limits. This qualification has a minor impact on the data usability. The reporting limit for the PAHs was 2.0 µg/kg. On average, the detection limits after blank qualification were less than five times the original reporting limit. With the exception of six results for acenaphthene, where the blank qualified nondetect result was higher than acenaphthene's PAL, all nondetects at raised detection limits were below PALs. For the six acenaphthene results, the highest raised detection limit was 50% higher than the PAL. Poor field duplicate precision was also noted for the sediment PAH analysis, although the concentrations of target PAHs in the parent and field duplicate sample had higher concentrations of PAHs (generally one to two orders of magnitude) than other samples, suggesting that these elevated concentrations were consistently detected at this location. Therefore, the data are considered usable for the project. The 90% completeness goal for all samples was met.

Table F.1 Quality Control Sample Summary Table

Medium/ Matrix	Analytical Parameter	Analytical Method	No. of Field Duplicate Pairs	Organic		Inorganic		No. of Trip Blanks	No. of Equipment Blanks	No. of PE Samples

Mr. Andy Schkuta
Metcalf & Eddy, Incorporated
701 Edgewater Drive
Wakefield, Massachusetts 01880

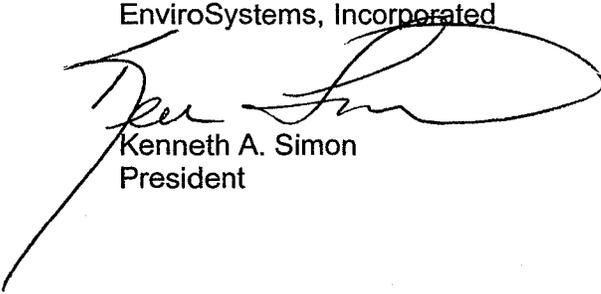

Dear Mr. Schkuta

Enclosed, please find two (2) copies of our final report evaluating the toxicity of sediment samples collected as part of the Iron Horse Park Sediment Evaluation. Sediment toxicity was evaluated during October 2004 using the freshwater midge, *Chironomus tentans* and amphipod, *Hyalella azteca*. Sediment toxicity was also evaluated by Microtox®. The Microtox® results can be found in Appendix A.

Please do not hesitate to call me or Brian Buzby should you have any questions or comments on the report.

Sincerely,

EnviroSystems, Incorporated

Kenneth A. Simon
President

Chronic Exposure Sediment Toxicity Tests**

Client Reference: W/A #158-RICO-0157
EPA RAC Contract # 68-W6-0042

1.0 INTRODUCTION

Toxicity tests expose groups of organisms to environmental samples, a laboratory control and/or a field reference site for a specified period to assess potential impacts on a variety of endpoints, such as survival, growth or reproduction. Analysis of variance techniques are used to determine the relative toxicity of the samples as compared to the laboratory control and/or field reference site.

This report presents the results of chronic exposure, survival and growth, toxicity tests conducted on five samples collected from the Iron Horse Park in central Massachusetts. The samples were provided by Metcalf & Eddy, Inc., Wakefield, Massachusetts. Testing was based on programs and protocols developed by the ASTM (2001) and US EPA (2000). The toxicity of the samples was assessed by conducting toxicity tests using the freshwater midge, *Chironomus tentans* and amphipod *Hyalella azteca*. Assays and supporting analyses were performed at EnviroSystems, Incorporated (ESI), Hampton, New Hampshire.

2.0 MATERIALS AND METHODS

2.1 General Methods, Biological Evaluations

Toxicological and analytical protocols used in this program follow procedures outlined in *Test Methods for Measuring the Toxicity of Sediment-Associated Contaminants with Freshwater Invertebrates* (ASTM 2001), *Methods for Measuring the Toxicity and Bioaccumulation of Sediment-associated Contaminants with Freshwater Invertebrates* (US EPA 2000) and *Standard Methods for the Examination of Water and Wastewater*, 20th Edition (APHA 1998). These protocols provide standard approaches for physical and chemical analysis and for the evaluation of toxicological effects of sediments on aquatic invertebrates.

2.2 Test Species

C. tentans were obtained from Aquatic Research Organisms, Inc., Hampton, New Hampshire. Larvae were classed as second instar and were approximately 13 days old at the start of the assay. Organisms were received at ESI the day prior to starting the assays. Organisms were held in natural surface water prior to the start of the assay.

H. azteca were obtained from Aquatic Research Organisms (ARO), Hampton, New Hampshire. Organisms were approximately 10 days old at the start of the assay. Organisms were

received at ESI the day prior to starting the assays. Organisms were held in a mix of moderately hard and natural surface water prior to the start of the assay.

2.3 Test Samples and Laboratory Control Sediment

2.3.1 Test Samples

A total of twenty-three (23) sediment samples from the Iron Horse Park project site were received at ESI between September 14 and September 21, 2004. Once received, samples were inspected, to determine integrity, given unique sample numbers and logged into the laboratory sample management database. Once logged into the sample management database samples were placed in a secure refrigerated, 2 - 4 °C, storage area until required. A listing of sample description, collection and receipt information is summarized in Table 1.

Prior to use in the assays sediments were screened using a MicroTox® solid phase screening assay. Results of the screening assays are provided in a Appendix A. Data from the screening assays was transmitted to Metcalf & Eddy on completion of the tests. The Metcalf & Eddy staff then provided ESI with a list of 5 samples to be evaluated using the 10-day acute exposure amphipod and midge larvae assays.

2.3.2 Control Sediments and Overlying Waters

For the midge larvae, the control substrate was an artificial sediment consisting primarily of silica sand, with approximately 2-3% organic material, by weight, added to the sand (EnviroSystems SOP QA-1470). Overlying water was a natural surface water collected from Bow Lake, Strafford, New Hampshire. Use of natural surface water over an artificial reconstituted water is recommended by the protocol (EPA 2000, ASTM 2001).

The amphipod assay laboratory control substrate was an artificial sediment consisting primarily of silica sand, with approximately 2-3%, by weight, of natural detritus. The detritus was collected above the water line in the pond but in a damp area. The top 0.5 to 1.0 cm of the sediment was collected. The organic detritus was mixed into the silica sand. Overlying water was a mix of moderately hard synthetic and natural surface water. The surface water was collected from Bow Lake, Strafford, New Hampshire. Use of synthetic/natural surface water over an artificial reconstituted water is recommended by the protocol (EPA 2000, ASTM 2001).

2.4 *Chironomus tentans* Survival and Growth Assays

The 10-day midge survival and growth evaluation sediment tests were conducted according to ASTM method E 1706-95 (ASTM 2001) and EPA method 100.5 (EPA 2000). Endpoints of the 10 day exposure were survival and growth, measured as ash free dry weight. The tests were started on October 5 and terminated on October 15, 2004.

The site sediment and laboratory control sediment treatments consisted of 8 replicates with 10 organisms/replicate. Test vessels were 400 mL glass beakers containing approximately 100 mL of sediment and 250 mL of overlying water. Test vessels were drilled at a consistent height above their bases and the hole covered with Nytex® screen. The screened hole facilitated water exchange without compromising organisms. The overlying water volume to sediment surface area ratio was approximately 7:1. Vessels were maintained in a water bath during the assay. Depth of the water in the bath was set to be approximately 1 cm below the drain hole in the test vessel to eliminate flow of water from the bath into the test vessel. The water bath was maintained in a limited access, temperature controlled room. Temperatures in the room and water bath were independently maintained at $23 \pm 1^\circ\text{C}$. The photoperiod in the test chamber was set at 16:8 hour light:dark. Light was provided by cool white fluorescent bulbs.

The day prior to test initiation (day -1), control and test sediments were sieved using a 2 mm sieve to remove rocks, twigs, and other debris. Sediments were placed in the test vessels. Overlying water was immediately added, and the vessels were left undisturbed overnight to settle. Floating detritus was removed the next morning. On day 0, larvae were added below the water surface of each test vessel.

Overlying water in each replicate was renewed daily after collection of water quality data. The volume of water added to each test chamber was approximately 500 mL, two volumes. Water exchanges were facilitated by use of a distribution system designed to provide equal, regulated, flow to each chamber. The system was activated manually by the addition of the water.

Prior to the daily overlying water renewal, temperature, specific conductance, pH, and dissolved oxygen were measured in one replicate of each treatment. Temperature data collected in a surrogate test chamber on an hourly basis during the 10 day exposure period documented a mean temperature of 24.5°C with values ranging from 20.0 to 25.5°C . Alkalinity, ammonia, and hardness of the overlying water were measured at the beginning and end of the assay. Water quality data are presented in Table 7. Daily overlying water quality records are available in Appendix A. Each replicate was fed 1.5 mL of a 6 g/L Tetramin® flake fish food suspension after the daily renewal.

After 10 days exposure, all replicates of each test treatment were terminated to collect data for the initial survival and growth portion of the tests. Each test chamber was gently swirled to loosen the sediments and the test material was dumped into an 8" stainless steel sieve with a 0.5 mm mesh screen. The sediments were washed through the sieve using synthetic, moderately hard reconstituted water and material left on the screen was sorted to recover of the organisms. This process was continued until the entire sample was evaluated. Surviving larvae were placed on tared weighing pans; partially and fully emerged organisms were recorded in survival counts but not included in weight measurements. Pans were dried overnight at 70°C to obtain dry weight to the nearest 0.01 mg. The organisms were then fired in a muffle furnace for two hours at 550°C to obtain the ash free dry weight to the nearest 0.01 mg. The mean weight of surviving organisms was determined to assess growth.

2.5 *H. azteca* Survival and Growth Assays

The 10 day amphipod survival and growth tests were conducted according to ASTM Method E 1706-95 (ASTM 2001) and EPA method 100.4 (EPA 2000). Endpoints of the 10 day exposure were survival and growth, measured as dry weight. The tests were started on October 5 and terminated on October 15, 2004.

The site sediment and laboratory control sediment treatments consisted of 8 replicates with 10 organisms/replicate. Test vessels were 400 mL glass beakers containing approximately 100 mL of sediment and 250 mL of overlying water. The overlying water volume to sediment surface area ratio was approximately 7:1. Test vessels were drilled at a consistent height above their bases and the hole covered with Nytex® screen. The screened hole facilitated water exchange without compromising organisms. Vessels were maintained in a water bath during the assay. Depth of the water in the bath was set to be approximately 1 cm below the drain hole in the test vessel to eliminate flow of water from the bath into the test vessel. The water bath was maintained in a limited-access temperature controlled room. Temperatures in the room and water bath were independently maintained at $23 \pm 1^\circ\text{C}$. The photoperiod in the test chamber was set at 16:8 hour light:dark. Light was provided by cool white fluorescent bulbs.

One day prior to test initiation (Day -1), control and test sediments were sieved using a 2 mm sieve to remove rocks, twigs, and other debris. Sediments were placed in the test vessels. Overlying water was immediately added, and the vessels were left undisturbed overnight to settle. Floating detritus was removed the next morning. On Day 0, organisms were added below the water surface of each test vessel.

Overlying water in each replicate was renewed daily after collection of water quality data. The volume of water added to each test chamber was approximately 500 mL or two volumes. Water exchanges were facilitated by use of a distribution system designed to provide equal, regulated, flow to each chamber. The system was activated manually by the addition of water during the assay.

Prior to the daily overlying water renewal, temperature, specific conductance, pH, and dissolved oxygen were measured in one replicate of each treatment. Temperature data collected in a surrogate test chamber collected on a hourly basis during the 10 day exposure period documented a mean temperature of 24.5°C with values ranging from 20.0 to 25.5°C . Alkalinity, ammonia, and hardness of the overlying water were measured at the beginning and end of the assay. Water quality data are presented in Table 7. Daily overlying water quality records are available in Appendix A. Each replicate was fed 1.0 mL of a yeast/trout chow/alfalfa suspension after the daily renewal.

After 10 days exposure, all replicates of each test treatment were terminated to collect data for the survival and growth endpoints. Each test chamber was gently swirled to loosen the sediments and the test material was dumped into an 8" stainless steel sieve with a 0.35 mm mesh screen. The sediments were washed through the sieve using synthetic, moderately hard reconstituted water and material left on the screen was sorted to recover of the organisms. This process was continued until the entire sample was evaluated. Organisms recovered were set aside to determine growth. Surviving amphipods were counted and placed on tared weighing pans. Pans were dried overnight at 70°C to obtain dry weight to the nearest 0.01 mg. The mean dry weight of surviving organisms was determined to assess growth.

2.6 Statistical Analysis

Endpoints were analyzed using CETIS® (Comprehensive Environmental Toxicity Information System) software to determine significant differences between the test sediments and the laboratory control sediment. Data sets were evaluated to determine normality of distribution and homogeneity of sample variance. Data sets were subsequently evaluated using the appropriate parametric or non-parametric Analysis of Variance (ANOVA) statistic. Pair-wise comparisons were made using the most appropriate two sample analysis. Statistical difference was evaluated at $\alpha=0.05$. Statistical comparisons were made against the laboratory control treatment and the project's reference site.

2.7 Quality Control

As part of the laboratory quality control program, reference toxicant evaluations are conducted by ESI on a regular basis for each test species. These results provide relative health and response data while allowing for comparison with historic data sets. Results were within two standard deviations of ESI's historic mean for the species. Results are summarized in Table 8.

2.8 Protocol Deviations

Review of data collected during this series of assays documented the following deviations from the prescribed protocol. Review of water quality parameters collected at the beginning and end of the assays documented a greater than 50% change in the alkalinity, ammonia, hardness and conductivity levels of the overlying water between the start and end of the chironomid assay. A similar deviation was noted for the alkalinity and ammonia levels in the amphipod assay. Review of the water quality data collected on the renewal water used in the assays documented, that prior to being added to the test chambers, there was less than a 50% change in concentration for the identified parameters between the start and end of the assay. The changes reported in the test chambers reflect the influence of the substrate on the water quality parameters.

It is the opinion of the study director that the protocol deviations recorded as part of a review of the project data had no significant impact on the overall outcome of the assays.

3.0 TOXICOLOGICAL TESTING RESULTS AND DISCUSSION

Chironomid survival and growth data are summarized in Tables 2 and 3, respectively. Amphipod survival and growth data from day 10 are summarized in Tables 4 and 5, respectively. Water quality data collected during the assays is summarized in Table 6 and 7. Reference toxicant data is summarized in Table 8. Support data, including copies of laboratory bench sheets, individual endpoint summaries and statistical analysis data printouts are provided in Appendix A.

3.1 *Chironomus tentans* Survival and Growth Evaluation

At the end of the 10 day exposure period, mean survival in the laboratory control sediment was 83.8%. Larvae recovered from the laboratory control sediment had a mean ash free dry weight of 2.03 mg/larvae. The minimum acceptable criteria for survival in the laboratory control is 70% and the minimum acceptable criteria for growth is a mean ash free dry weight of 0.48 mg/larvae. These data indicate that the organisms were healthy and not stressed by handling.

Chironomid survival in the project reference site sediment (SED-22) at the end of the 10-day exposure period was 77.5%, with individual replicates ranging from 70 to 100%. Surviving midge larvae had a mean ash free dry weight of 1.84 mg/larvae. Survival and growth of midge larvae maintained in the reference site sediment was not statistically less from that observed in the laboratory control.

Tables 2 and 3 summarize the survival and growth results associated with all five sediment sites.

3.2 *Hyalella azteca* Survival and Growth Evaluation

At the end of the 10 day exposure period, mean survival in laboratory control sediment was 100%. Amphipods recovered from laboratory control sediment had a mean dry weight of 0.080 mg/amphipod. The dry weight of a representative group of amphipods at the start of the assay was 0.030 mg/individual. The minimum test acceptability criteria for survival in the laboratory control is 80%. The minimum acceptable criteria for growth is a demonstration of increased dry weight after 10 days exposure. These data indicate that the organisms were healthy and not stressed by handling.

Amphipod survival in the project reference site sediment (SED-22) at the end of the 10-day exposure period was 92.5% survival, with individual replicates ranging from 80 to 100%. Surviving amphipods had a mean dry weight of 0.078 mg/amphipod. Survival but not growth of the amphipods maintained in the reference site sediment was statistically less than that observed in the laboratory control.

Tables 4 and 5 summarize the survival and growth results associated with all five sediment sites.

3.3 Summary

3.3.1 *Chironomus tentans* Test Summary

Review of survival data showed that after 10 days exposure survival of chironomids maintained in sediment from site SED-11 was significantly less as compared to the laboratory control, but not as compared to the reference site sediment. Analysis of growth data, ash free dry weight, showed that larvae maintained in sediment from SED-05, SED-11 and SED18 project sites exhibited statistically lower growth when compared to both the laboratory control and project reference site sediment.

3.3.2 *Hyalella azteca* Test Summary

Review of survival data showed that after 10 days exposure survival of amphipods maintained in sediments from sites SED-01, SED-05, SED-11 and SED18 was significantly less as compared to the laboratory control. When statistical comparisons for survival were made against the project reference site survival in sediment from site SED-18 was found to be significantly less.

Analysis of growth data showed that amphipods maintained all four sediment project sites did not exhibit statistically lower growth as compared to both the laboratory control and the project reference site sediment.

Aquatic Research Organisms

DATA SHEET

I. Organism History

Species: Chironomus dilutus

Source: Lab reared Hatchery reared _____ Field collected _____

Hatch date _____ Receipt date _____

Lot number 092204CT Strain ARO

Brood Origination _____

II. Water Quality

Temperature 24 °C Salinity ~ ppt DOSAT _____

pH 7.4 Hardness ~120 ppm

III. Culture Conditions

System: Fw static renewal

Diet: Flake Food Phytoplankton _____ Trout Chow

Brine Shrimp _____ Rotifers _____ Other Algae

Prophylactic Treatments: _____

Comments: _____

IV. Shipping Information

Client: EST # of Organisms: 600

Carrier: Pick-up Date Shipped: 10/5/04

Biologist: [Signature]

1 - 800 - 927 - 1650

PO Box 1271 • One Lafayette Road • Hampton, NH 03842 • (603) 926-1650

Aquatic Research Organisms

DATA SHEET

I. Organism History

Species: Hyalinella azteca

Source: Lab reared Hatchery reared _____ Field collected _____

Hatch date 9/28/04 Receipt date _____

Lot number 092804HA Strain ARO

Brood Origination USFWS MO

II. Water Quality

Temperature 23 °C Salinity - ppt DO Sat

pH 7.0 Hardness 120 ppm

III. Culture Conditions

System: PW STATIC RECYCLING

Diet: Flake Food Phytoplankton _____ Trout Chow

Brine Shrimp _____ Rotifers _____ Other _____

Prophylactic Treatments: _____

Comments: _____

IV. Shipping Information

Client: EST # of Organisms: 600

Carrier: PICK UP Date Shipped: 10/5/04

Biologist: Ston Santape

Dear Mr. Schkuta

Enclosed, please find two (2) copies of our final report evaluating the toxicity of water samples collected as part of the Iron Horse Park Sediment Evaluation. Toxicity was evaluated during September 2004 using the daphnid, *Ceriodaphnia dubia*, and minnow, *Pimephales promelas*.

Please do not hesitate to call me or Brian Buzby should you have any questions or comments on the report.

Sincerely,

EnviroSystems, Incorporated

Kenneth A. Simon
President

TOXICOLOGICAL EVALUATION OF SURFACE WATER SAMPLES

Ceriodaphnia dubia and *Pimephales promelas* Surface Water Toxicity Tests Iron Horse Park Surface Water Evaluation

1.0 INTRODUCTION

Toxicity tests expose groups of organisms to environmental samples and a laboratory control and/or a field reference site for a specified period to assess potential impact on survival and growth. Chronic toxicity tests measure sublethal effects, exposing test organisms to samples during a sensitive period in the life cycle. Analysis of variance techniques are used to determine the relative toxicity of the samples as compared to the laboratory control and/or field reference site.

This report presents the results of chronic toxicity tests conducted on five surface water samples collected from the Iron Horse Park project site. Surface water samples were provided by Metcalf and Eddy, Inc. staff from the Wakefield, Massachusetts office. Testing was based on programs and protocols developed by the US EPA (2002). The toxicity of the samples was assessed by conducting chronic renewal toxicity tests using the daphnid, *Ceriodaphnia dubia* and fathead minnow, *Pimephales promelas*. Assays and supporting analyses were performed at EnviroSystems, Incorporated (ESI), Hampton, New Hampshire.

2.0 MATERIALS AND METHODS

2.1 General Methods

Toxicological and analytical protocols used in this program follow procedures outlined in *Short-Term Methods for Estimating the Chronic Toxicity of Effluents and Receiving Waters to Freshwater Organisms* (EPA 2002), and *Standard Methods for the Examination of Water and Wastewater*, 20th Edition (APHA 1998). These protocols provide standard approaches for physical and chemical analysis and for the evaluation of toxicological effects of surface waters on aquatic organisms.

2.2 Test Species

C. dubia, cultured at ESI, were maintained in laboratory water at 25±1°C with a photoperiod of 16:8 hours light:dark. Cultures are fed daily with a yeast/trout chow/Cerophyll or alfalfa leaves (YTC) mixture supplemented with *Selenastrum capricornutum* (algae) (EPA 2002). Organisms used in the assay were <24 hours old juveniles, released within 8 hours of one another, and from broods of ≥8 juveniles.

P. promelas, ≤24 hours old, were obtained from Aquatic Bio Systems, Incorporated, Fort Collins, Colorado, and Aquatic Research Organisms, Hampton, New Hampshire. Test organisms were transferred from acclimation tanks to test chambers using a large bore glass pipet, minimizing the amount of water added to the test sample.

2.3 Test Samples and Laboratory Control Water

Five (5) surface water samples collected from the Iron Horse Park project site for *C. dubia* and *P. promelas* testing were received at ESI between September 23 and September 25, 2004. Upon arrival at the laboratory, the samples were given an internal sample control number and logged into the project sample control system. Prior to testing, samples were placed in a secure refrigerator and stored at a temperature of 2-4°C until test initiation. Sample identification, collection and receipt information is summarized in Table 1. Samples were warmed to the appropriate test temperature prior to testing. Due to holding time considerations, samples were analyzed as they were received with each group or samples received its own laboratory control treatment.

Laboratory control water for the daphnid and minnow assays was synthetic, soft, reconstituted water prepared at ESI according to protocol (EPA 2002). This water has been used to successfully culture fresh water test organisms since 1992.

2.4 *C. dubia* Survival and Reproduction Assay

The chronic toxicity tests were conducted according to EPA method 1002.0, which called for the daily renewal of test solutions (EPA 2002). Protocol suggests that surface water samples are evaluated as 100% surface water with a laboratory control (EPA 2002). Iron Horse Park project site test replicates were renewed with the appropriate site specific surface water sample. Endpoints of the assay were survival and reproduction. Testing occurred between September 23, 2004 and October 1, 2004; testing was completed in three separate testing events, each supported by its own laboratory control (see Table 1). Each daphnid testing event was 7 days in duration.

Test chambers for the chronic exposure daphnid assays were 30 mL portion cups containing 20 mL of test solution in each of 10 replicates with 1 organism/replicate. Survival and juvenile production were monitored daily. Dissolved oxygen, pH, conductivity and temperature were measured in each new test solution. Daphnids were fed 200 µL each of YTC and algae as part of the daily renewals.

2.5 *P. promelas* Survival and Growth Assay

The 7-day surface water tests were conducted according to EPA method 1000.0, which called for the daily renewal of test solutions (EPA 2002). Protocol suggests that surface water samples are evaluated as 100% surface water with a laboratory control (EPA 2002). Iron Horse Park project site test replicates were renewed with the appropriate site specific surface water sample. Endpoints of the assay were survival and growth. Testing occurred between September 23, 2004 and October 1, 2004; testing was completed in three separate testing events, each supported by its own laboratory control.

All assays incorporated four replicates with 10 organisms/replicate. Test vessels were 400 mL glass beakers containing approximately 250 mL of solution. Dissolved oxygen, pH, temperature, and conductance were measured in one replicate of each new test solution. Vessels were maintained in a temperature-controlled incubator during testing. Temperature in the incubator was maintained at 25 ±1°C. The photoperiod in the test chamber was set at 16:8 hour light:dark. Light was provided by cool white fluorescent bulbs.

Prior to daily minnow renewals, survival and dissolved oxygen were measured in all replicates, and pH, temperature and specific conductance were measured in one replicate of each test treatment. Alkalinity, ammonia, and hardness of the surface water and laboratory control water treatments were measured on Day 0. Fish were fed newly hatched *Artemia* nauplii daily. Dead nauplii from previous feedings were removed during daily renewals.

On Day 7 of the assay, surviving fish were euthanized using Finquel® tricaine methanesulfonate and rinsed with DI water to remove any surface detritus that may interfere with the weighing process. Fish were placed on tared weighing pans and dried overnight at 104°C to obtain dry weight to 0.01 mg. Final dry weight/fish for statistical comparisons was calculated by dividing the net dry weight by the number of organisms introduced on Day 0.

2.6 Statistical Analysis

Survival and reproduction data were analyzed using TOXSTAT® software to determine significant differences between the test samples and their associated laboratory controls and reference sites. Statistical comparisons for each sample site were made against the associated laboratory control and project reference site. Survival and reproduction data were evaluated to determine homogeneity of sample variances and normality of distribution using Shapiro-Wilk's Test for Normality and the F-Test for Equality of Two Variances, respectively. Data sets were subsequently evaluated using the appropriate parametric or non-parametric Analysis of Variance (ANOVA) statistic. Pair-wise comparisons were based on the 2 sample t-Test. Statistical difference was evaluated at $\alpha=0.05$. In cases where the observed endpoint in the treatment was greater than that observed in the laboratory control and reference site sample no statistical evaluation was conducted.

2.7 Quality Control

As part of the laboratory quality control program, reference toxicant evaluations are conducted by ESI on a regular basis for each test species. These results provide relative health and response data while allowing for comparison with historic data sets. Results were within one standard deviation of ESI's historic mean for the species. Results of these tests are presented in Table 7.

2.8 Protocol Deviations

Review of testing procedures and data generated from testing indicated one deviation from standard protocols. Sample SW-MC-01 lost two minnows from Replicate D on Day 2 due to a technician error. All statistical analysis for this replicate was therefore based upon the assumption that eight fish instead of ten were added at the start of testing. It is the opinion of the Study Director that this deviation had no negative impact on the outcome of the assay.

3.0 RESULTS AND DISCUSSION

Survival and reproduction data from the *C. dubia* assays are summarized in Tables 2 and 3, respectively, while *P. promelas* survival and growth data are summarized in Tables 4 and 5. Water quality data collected during the assays is summarized in Table 6. Reference toxicant data for the organisms is summarized in Table 7. Support data, including copies of laboratory bench sheets, are provided in Appendix A.

3.1 *C. dubia* Chronic Exposure Survival and Reproduction Assays

For the three separate exposure periods, laboratory control survival in each series was 100%. Reproduction, measured as number of juveniles produced per female, ranged from 28.4 to 33.7 juveniles per female. Three or more broods were produced by 100% of the laboratory water control females by the end of each of the three exposures. Minimum test acceptability criteria require 80% survival, mean production of 15 juveniles/female, and production of 3 broods by at least 60% of control animals (EPA 2002). These results are an indication of healthy test organisms.

Review of data generated during the three sets of daphnid assays showed survival in waters from the project sites ranged from 70% to 100%. Statistical analysis of the data showed that survival of daphnids maintained in water from site SW-RF-01 was the only site where survival, when compared to the laboratory control, was negatively impacted. Comparison of juvenile production showed mean numbers of juveniles produced by daphnids maintained in project surface waters ranged from 21.9 to 33.2 juveniles per adult. Statistical comparisons of the reproduction data against the laboratory controls showed that reproduction in the project sites SW-RP-01 and SW-RF-01 was negatively impacted. Statistical comparisons of the reproduction data against site SW-RF-01 showed that reproduction in the other project sites was not statistically different from that observed at SW-RF-01. Tables 2 and 3 provide a summary of survival and reproduction data for the laboratory controls and project sites.

3.2 *P. promelas* Chronic Exposure Survival and Growth Assays

At the end of the three separate assays, laboratory control survival ranged from 87.5 to 100%. Growth, measured as mean dry weight, ranged from 0.448 to 0.482 mg/fish. Minimum test acceptability criteria require 80% survival and mean dry weight of 0.250 mg/fish. (EPA 2002). These results are an indication of healthy test organisms.

Review of minnow survival data from the project sites for the three series of assays showed survival rates ranging from 61.25% to 100%. Results of statistical analyses conducted with the associated laboratory control treatments show that minnow survival in the SW-MC-01 site was statistically less than that observed in the associated control. A statistical comparison of survival between sites SW-RF-01 and SW-MC-01 showed survival in SW-MC-01 was significantly less than that observed for SW-RF-01. Mean dry weight in the project sites ranged from 0.346 mg/fish to 0.534mg/fish. No project sites showed growth significantly less than the laboratory controls. Statistical comparisons of growth made against the SW-RF-01 site showed that minnow growth from site SW-CB-01 was statistically less than that observed for site SW-RF-0. Tables 4 and 5 provide a summary of survival and growth data for the laboratory controls and project sites.

3.3 Summary

Results of the chronic exposure daphnid assays document that one of the surface water samples evaluated, SW-RF-01, had a significant negative impact on daphnid survival when compared to the associated laboratory control. Review of reproduction data indicated significant negative impacts on daphnid juvenile production in water from two sites, SW-RP-01 and SW-RF-01, when evaluated against the associated laboratory control. Statistical comparisons for survival and reproduction made against the SW-RF-01 site showed no statistically significant negative effects.

Review of chronic exposure minnow assays documented that survival and growth in one project site water, SW-MC-01, was significantly impacted when compared to the laboratory control and site SW-RF-01.

Shapiro - wilk's Test for Normality

D = 1.6000

W = 0.6032

Critical W = 0.8680 (alpha = 0.01 , N = 20)

W = 0.9050 (alpha = 0.05 , N = 20)

Data FAIL normality test (alpha = 0.01). Try another transformation.

Warning - The F-test of homogeneity is sensitive to non-normality and should not be performed with this data as is.

File: mecds24

Transform:

NO TRANSFORMATION

F-Test for Equality of Two Variances

GROUP	IDENTIFICATION	VARIANCE	F
1	Lab 00a	0.0000	
2	-024	0.1778	99999.0000

(p-value = 0.0000)

Critical F = 6.5411 (P=0.01, 9, 9)

4.0260 (P=0.05, 9, 9)

Since F > Critical F, REJECT Ho: Equal Variances (alpha = 0.01).

NOTE: This test requires positive variances. If one of the variances is zero, the test will always reject Ho: Equal Variances.

Title: STUDY 12551: Cerio Survival
File: mecds33 Transform: ARC SINE(SQUARE ROOT(Y))

Shapiro - Wilk's Test for Normality

D = 0.2467
W = 0.4049

Critical W = 0.8680 (alpha = 0.01 , N = 20)
W = 0.9050 (alpha = 0.05 , N = 20)

Data FAIL normality test (alpha = 0.01). Try another transformation.

Warning - The F-test of homogeneity is sensitive to non-normality and should not be performed with this data as is.

Title: STUDY 12551: Cerio Survival
File: mecds33 Transform: ARC SINE(SQUARE ROOT(Y))

F-Test for Equality of Two Variances

GROUP	IDENTIFICATION	VARIANCE	F
1	Lab 00b	0.0000	
2	-033	0.0274	99999.0000

(p-value = 0.0000)

Critical F = 6.5411 (P=0.01, 9, 9)
4.0260 (P=0.05, 9, 9)

Since F > Critical F, REJECT Ho: Equal Variances (alpha = 0.01).

NOTE: This test requires positive variances. If one of the variances is zero, the test will always reject Ho: Equal Variances.

Critical Chi-Square = 13.277 (alpha = 0.01 , df = 4)
 = 9.488 (alpha = 0.05 , df = 4)

Data PASS normality test (alpha = 0.01). Continue analysis.

Shapiro - Wilk's Test for Normality

D = 994.9000
 W = 0.8660

Critical W = 0.8680 (alpha = 0.01 , N = 20)
 W = 0.9050 (alpha = 0.05 , N = 20)

Data FAIL normality test (alpha = 0.01). Try another transformation.

Warning - The F-test of homogeneity is sensitive to non-normality and should not be performed with this data as is.

F-Test for Equality of Two Variances

GROUP	IDENTIFICATION	VARIANCE	F
1	Lab	24.0000	
2	-32	86.5444	3.6060

Critical F = 6.5411 (P=0.01, 9, 9) (p-value = 0.0696)
 4.0260 (P=0.05, 9, 9)

Since F <= Critical F, FAIL TO REJECT Ho: Equal Variances (alpha = 0.01).

Title: STUDY 12551: Cerio Survival
 File: mecds3 Transform: ARC SINE(SQUARE ROOT(Y))

Shapiro - Wilk's Test for Normality

D = 0.5757
 W = 0.7258

Critical W = 0.8680 (alpha = 0.01 , N = 20)
 W = 0.9050 (alpha = 0.05 , N = 20)

Data FAIL normality test (alpha = 0.01). Try another transformation.

Warning - The F-test of homogeneity is sensitive to non-normality
 and should not be performed with this data as is.

Title: STUDY 12551: Cerio Survival
 File: mecds3 Transform: ARC SINE(SQUARE ROOT(Y))

F-Test for Equality of Two Variances

GROUP	IDENTIFICATION	VARIANCE	F
1	Lab 00c	0.0000	
2	-040	0.0640	99999.0000

(p-value = 0.0000)

Critical F = 6.5411 (P=0.01, 9, 9)
 4.0260 (P=0.05, 9, 9)

Since F > Critical F, REJECT Ho: Equal Variances (alpha = 0.01).

NOTE: This test requires positive variances. If one of the variances
 is zero, the test will always reject Ho: Equal Variances.

Shapiro - Wilk's Test for Normality

D = 0.1384

W = 0.8910

Critical W = 0.7490 (alpha = 0.01 , N = 8)

W = 0.8180 (alpha = 0.05 , N = 8)

Data PASS normality test (alpha = 0.01). Continue analysis.

Title: Metcalf & Eddy P promelas Survival

File: ME Transform: ARC SINE(SQUARE ROOT(Y))

F-Test for Equality of Two Variances

GROUP	IDENTIFICATION	VARIANCE	F
1	Lab	0.0000	
2	-40	0.0461	99999.0000

(p-value = 0.0000)

Critical F = 47.4672 (P=0.01, 3, 3)

15.4392 (P=0.05, 3, 3)

Since F > Critical F, REJECT Ho: Equal Variances (alpha = 0.01).

NOTE: This test requires positive variances. If one of the variances is zero, the test will always reject Ho: Equal Variances.

- (1) Percent moisture measured in the field using HH2 Moisture Meter (Delta-T Devices), as noted on the Chain of Custody.
(2) Percent solids were calculated after samples were partially dried with coffee filters (for wet weight) and after drying in the toaster oven (for dry weight).

E Estimated value; exceeds upper limit of calibration

- (1) Percent moisture measured in the field using HH2 Moisture Meter (Delta-T Devices), as noted on the Chain of Custody.
- (2) Percent solids were calculated after samples were partially dried with coffee filters (for wet weight) and after drying in the toaster oven (for dry weight).

Required QC:
 Instrument blank: Prior to sample analysis, every 2 hours, and at end of sample analysis
 Method blank: Prior to sample analysis
 Duplicate readings: One per 20 samples or one per day, whichever is more frequent
 Replicate measurements: One per 20 samples or one per day, whichever is more frequent
 Precision samples: One per day

MDL Study: Once at onset of program using NIST-low standard
 Record result ± standard deviation for each metal

Criteria:
 (Metals < detection limit)
 (Metals < detection limit)
 (RPD ≤ 35)
 (RPD ≤ 35)
 (% RSD ≤ 30 for Cr
 and % RSD ≤ 20 for remaining metals)
 NA

DATA SUMMARY TABLE DEFINITIONS (Inorganics)

- BB - As a qualifier for soil/sediment samples: Analyte is also detected in the bottle blank
- CRQL - Contract Required Quantitation Limit
- EB - As a qualifier for soil/sediment samples: Analyte is also detected in the equipment blank
- FD - Field Duplicate
- g - gram
- MDL - Method Detection Limit
- J - The concentration is an estimated quantity
- mg/Kg - milligrams per Kilogram
- mg/L - milligrams per Liter
- R - The data are rejected as unusable
- RL - Reporting Limit
- U - Analyte was analyzed for but not detected
- ug/Kg - micrograms per Kilogram
- ug/L - micrograms per Liter
- UJ - The sample quantitation limit is an estimated quantity
- NA - Not Applicable

DATA SUMMARY TABLE
DEFINITIONS (Inorganics)

BB - As a qualifier for soil/sediment samples: Analyte is also detected in the bottle blank
CRQL - Contract Required Quantitation Limit
EB - As a qualifier for soil/sediment samples: Analyte is also detected in the equipment blank
FD - Field Duplicate
g - gram
MDL - Method Detection Limit
J - The concentration is an estimated quantity
mg/Kg - milligrams per Kilogram
mg/L - milligrams per Liter
R - The data are rejected as unusable
RL - Reporting Limit
U - Analyte was analyzed for but not detected
ug/Kg - micrograms per Kilogram
ug/L - micrograms per Liter
UJ - The sample quantitation limit is an estimated quantity
NA - Not Applicable

DATA SUMMARY TABLE DEFINITIONS (Organics)

- BB - As a qualifier for soil/sediment samples: Compound is also detected in the bottle blank
- CRQL - Contract Required Quantitation Limit
- EB - As a qualifier for soil/sediment samples: Compound is also detected in the equipment blank
- FD - Field Duplicate
- g - gram
- J - The concentration is an estimated quantity
- kg - kilogram
- L - Liter
- mg/Kg - milligrams per kilogram
- mg/L - milligrams per liter
- ml - milliliter
- R - The data are rejected and unusable
- RL - Reporting Limit
- U - Compound was analyzed for but not detected
- ug/kg - micrograms per kilogram
- UJ - The sample quantitation limit is an estimated quantity
- ug/L - micrograms per liter

Geotechnical Test Report

November 9, 2004

Iron Horse Park Project

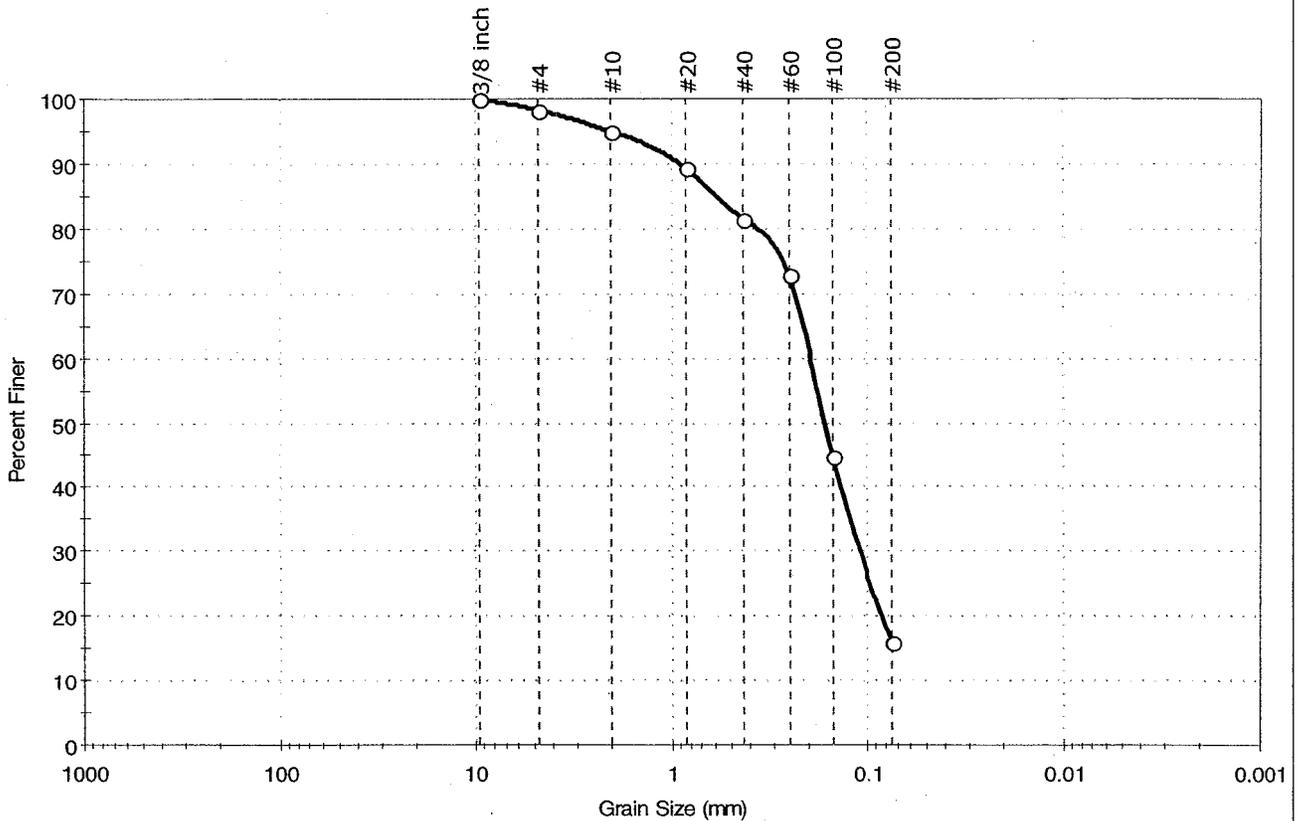

Billerica, MA

Prepared for:

Client: Metcalf & Eddy	Project No: GTX-5496	
Project: Iron Horse Park	Tested By: ahp	
Location: Billerica, MA	Sample Type: bag	Checked By: jdt
Boring ID: SED-01	Test Date: 10/06/04	Test Id: 61614
Sample ID: D05199	Sample Description: Wet, very dark brown silty sand	
Depth: ---	Sample Comment: ---	
Test Comment: Very high organic content		

Particle Size Analysis - ASTM D 422

%Cobble	%Gravel	%Sand	%Silt & Clay Size
—	1.8	82.3	15.9

Sieve Name	Sieve Size (mm)	Percent Finer	Spec. Percent	Complies
3/8 inch	9.51	100		
#4	4.75	98		
#10	2.00	95		
#20	0.84	89		
#40	0.42	81		
#60	0.25	73		
#100	0.15	45		
#200	0.075	16		

Coefficients

D ₈₅ = 0.5784 mm	D ₃₀ = 0.1052 mm
D ₆₀ = 0.1982 mm	D ₁₅ = N/A
D ₅₀ = 0.1651 mm	D ₁₀ = N/A
C _u = N/A	C _c = N/A

Classification

ASTM N/A

AASHTO Silty Gravel and Sand (A-2-4 (0))

Boring ID: SED-05	Sample ID: D05203	Test Date: 10/08/04
Depth: ---	Test Id: 61615	
Sample Description: Wet, very dark brown sand with silt		
Sample Comment: smell of petrolium		
Test Comment: very high organic content		

Particle Size Analysis - ASTM D 422

% Cobble	% Gravel	% Sand	% Silt & Clay Size
—	4.4	87.2	8.4

Sieve Name	Sieve Size (mm)	Percent Finer	Spec. Percent	Complies
3/8 Inch	9.51	100		
#4	4.75	96		
#10	2.00	72		
#20	0.84	52		
#40	0.42	37		
#60	0.25	25		
#100	0.15	16		
#200	0.075	8		

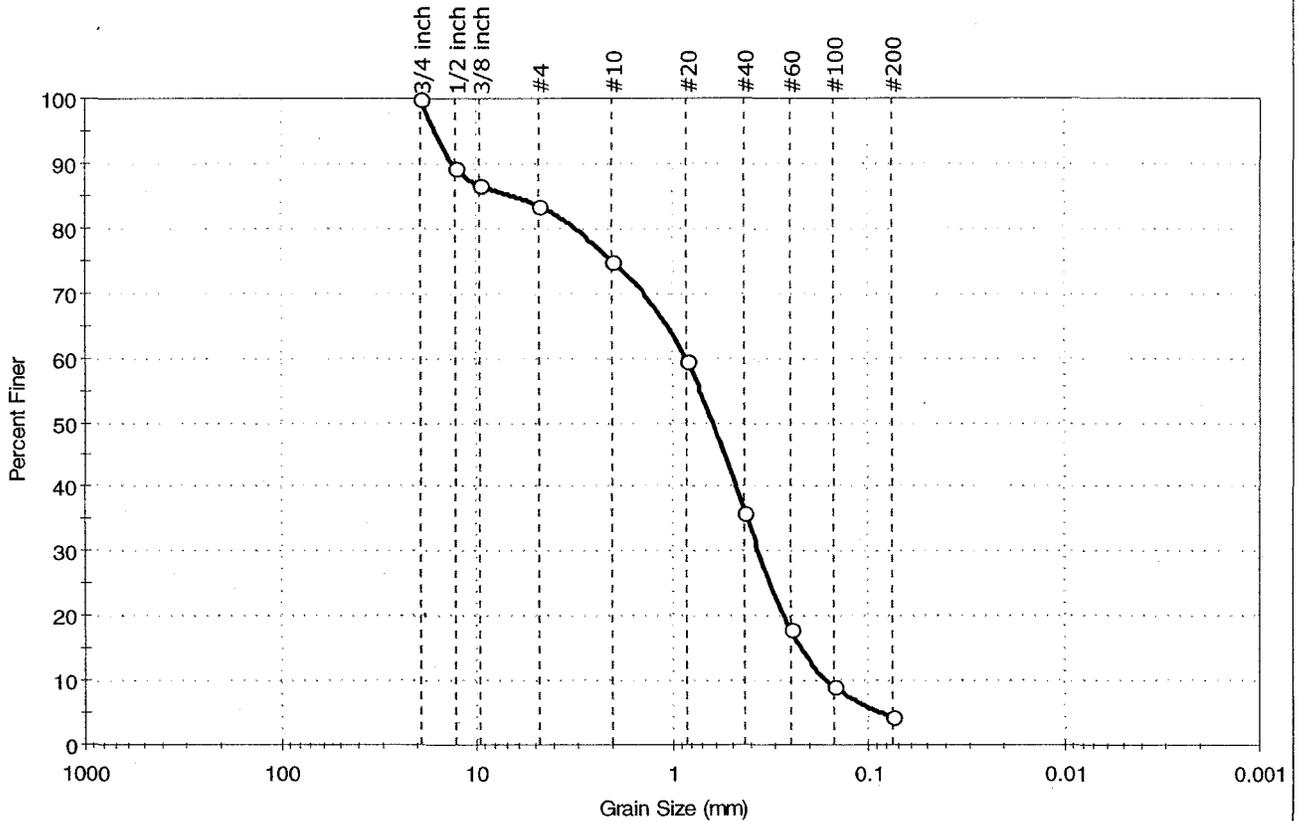

Coefficients	
D ₈₅ = 3.2046 mm	D ₃₀ = 0.3104 mm
D ₆₀ = 1.1704 mm	D ₁₅ = 0.1395 mm
D ₅₀ = 0.7558 mm	D ₁₀ = 0.0872 mm
C _u = 13.422	C _c = 0.082

Classification	
ASTM	N/A
AASHTO	Stone Fragments, Gravel and Sand (A-1-b (0))

Sample/Test Description
Sand/Gravel Particle Shape : ---
Sand/Gravel Hardness : ---

Client: Metcalf & Eddy	Project: Iron Horse Park	Project No: GTX-5496
Location: Billerica, MA	Boring ID: SED-11	Sample Type: bag
Sample ID: D05210	Test Date: 10/07/04	Tested By: ahp
Depth: ---	Test Id: 61616	Checked By: jdt
Sample Description: Wet, black sand with gravel and organics		
Sample Comment: ---		
Test Comment: ---		

Particle Size Analysis - ASTM D 422

%Cobble	%Gravel	%Sand	%Silt & Clay Size
---	16.6	79.1	4.3

Sieve Name	Sieve Size (mm)	Percent Finer	Spec. Percent	Complies
3/4 Inch	19.00	100		
1/2 Inch	12.70	89		
3/8 Inch	9.51	87		
#4	4.75	83		
#10	2.00	75		
#20	0.84	60		
#40	0.42	36		
#60	0.25	18		
#100	0.15	9		
#200	0.075	4		

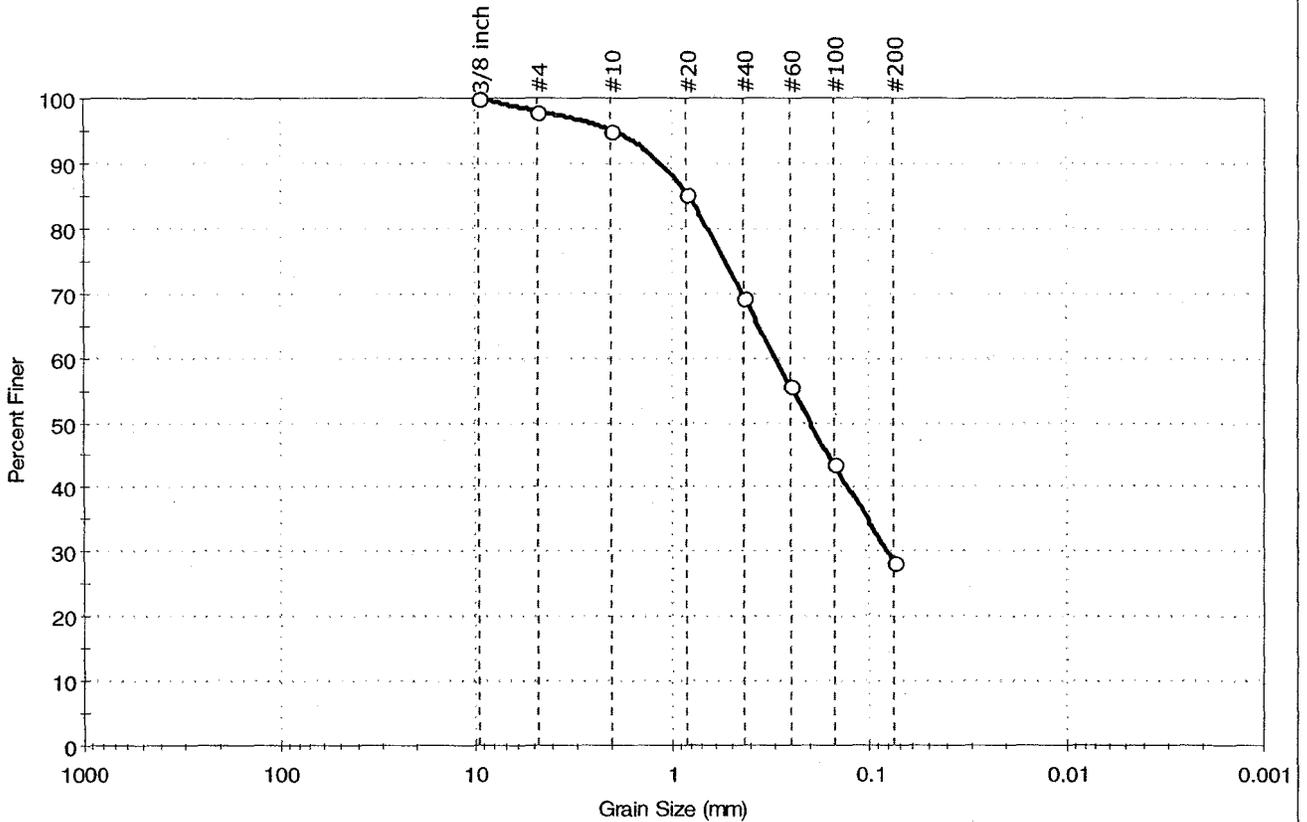

Coefficients	
D ₈₅ = 6.6323 mm	D ₃₀ = 0.3560 mm
D ₆₀ = 0.8575 mm	D ₁₅ = 0.2110 mm
D ₅₀ = 0.6360 mm	D ₁₀ = 0.1579 mm
C _u = 5.432	C _c = 0.148

Classification	
ASTM	Poorly graded sand with gravel (SP)
AASHTO	Stone Fragments, Gravel and Sand (A-1-b (0))

Sample/Test Description	
Sand/Gravel Particle Shape	: ---
