**NEW BEDFORD HARBOR THIN LAYER  
SEDIMENT SAMPLING PROGRAM**

**1.0 INTRODUCTION**

Following a review of existing data characterizing New Bedford Harbor sediments, it was determined that additional sediment quality data would permit better definition of the vertical distribution of PCBs and heavy metals in New Bedford Harbor sediment. As such, a sampling program to allow more accurately estimation of the rate of PCB and heavy metal flux was designed and implemented. This sediment sampling program was prepared by Dr. W. Frank Bohlen of the University of Connecticut and Balsam Environmental Consultants, Inc. (Balsam), and was subsequently undertaken under the direction of Balsam.

## 2.0 FIELD PROGRAM IMPLEMENTATION

During the week of December 12, 1988, Balsam and University of Connecticut personnel implemented the sample collection phase of this thin layer sediment sampling program. Prior to implementation of the field program, written protocols were developed for the conduct of this work. A copy of these protocols is included as Appendix A.

In developing these sampling protocols, two depositional regimes were identified as preferred sampling stations. One sampling station was to be located at an area in or adjacent to the so called "hot spot" area located east and southeast of the Aerovox, Inc. facility. The location of this sampling station, designated as Station FX, is shown on Figure 1.

The second preferred sampling area was to be located in an area of above average sediment deposition with moderately elevated PCB sediment concentrations. The southwestern cove of the upper estuary was selected as the location for this second sampling station. The sampling station selected to represent this sediment depositional regime, designated as Station DR, is also shown on Figure 1.

Following collection of sediment core samples from the two designated sampling stations, samples were transported by field sampling personnel to University of Connecticut laboratory facilities for further processing. Activities at the University of Connecticut laboratory included sectioning of samples into one to four centimeter thick subsections which were then delivered to an analytical laboratory for chemical analysis. Sample subsectioning protocols are included as part of Appendix A.

Following completion of sample subsectioning and labeling, samples were personally delivered to Cambridge Analytical Associates, Inc. (CAA) for chemical analysis of PCBs, mercury, chromium, copper, lead and zinc.

### 3.0 PROGRAM RESULTS

PCB and heavy metal analyses were performed on forty-four (44) sediment samples collected from the two sampling stations within the upper estuary, as well as additional quality assurance/quality control (QA/QC) samples. Analytical results for analysis of the twenty-two (22) sediment samples from each of Stations FX and DR are summarized in Tables 1 and 2; Table 1 presents results of PCB analyses, and Table 2 presents results of metals analyses. Analytical reports received from CAA are included as Appendix B.

Initial review of PCB analyses performed as part of this thin layer sediment sampling program indicate significant vertical stratification of PCBs in upper estuary sediments. In particular, the series of vertical subsection samples located in the vicinity of the area referred to as the "hot spot" indicated PCBs to be primarily present in the upper 12 inches (approximately 30 centimeters) of sediment, with only very low concentrations of PCBs (less than 1 part per million (ppm)) present at depths greater than 12 inches. It is also significant to note that the upper subsection samples collected from Station FX (i.e., 0-6 centimeters) were lower in PCB concentration than those collected from the 6-12 centimeter interval. The existing EPA sediment analytical database for the upper estuary, which is based primarily on 12-inch sediment intervals, may overestimate surficial sediment PCB concentrations in areas where elevated PCB concentrations are reported present in estuary sediments. As an example, the calculated weighted average total PCB concentration for the 0 to 12 inch sediment interval at Station FX is 3,060 ppm as shown in Table 3. However, as shown in Table 1, the surficial sediment (0 - 1 cm) at Station FX was reported to contain 1,600 ppm of PCB, or approximately half of the weighted average total PCB concentration calculated for the 0 to 12 inch sediment interval. Similar PCB depositional trends were also observed in the sample collected from the Station DR.

The weighted average PCB concentration was calculated in order to allow data from the thin layer sediment sampling program to be compared to existing analytical data. PCB weighted average concentrations were estimated for the 0 to 6 inch, 6 to 12 inch, and 0 to 12 inch sediment intervals at both stations FX and DR utilizing the thin layer sediment sampling analytical data. The weighted-averaging technique provides for weighting of each PCB concentration by the magnitude of the depth interval (1 cm to 4 cm) with which it was associated. To make these calculations, the following equation was used:

$$c = \frac{c_1 \times d_1}{d_t} + \frac{c_2 \times d_2}{d_t} + \frac{c_3 \times d_3}{d_t} + \dots + \frac{c_i \times d_i}{d_t}$$

where:        c        =        average concentration over depth  $d_t$   
                $c_i$      =        discrete sample concentration for depth interval  $d_i$   
                $d_i$      =        discrete depth interval  
                $d_t$      =        total depth interval

Thus, a PCB concentration from a 4 centimeter sediment interval sample was weighted twice as much as a PCB concentration from a 2 centimeter sediment interval sample. These estimates are presented as Table 3. Review of these estimates indicate that the majority of PCB present in the vicinity of sampling stations FX and DR is within the upper 6 inches of sediment.

In reviewing heavy metal analysis performed on samples from stations DR and FX, similar types of trends were also noted, although the depths of contamination and magnitude of concentration decline varied. As an example, a review of the chromium, copper, lead and zinc analytical data for Station FX showed moderate metals concentrations in surficial and near surface sediment samples (up to 6 centimeters in depth) as compared to somewhat deeper sediment samples (the 6 to 28 centimeter depth interval), and markedly reduced concentrations as sediment sample depth increased.

#### 4.0 ANALYTICAL DATA ASSESSMENT

As a means to evaluate the performance of the analytical laboratory as well as field protocol, a series of quality control (QC) samples were submitted to CAA. A total of six blind QC samples consisting of two duplicate sediment samples, two duplicate sediment control samples, one blank water sample, and one wash water sample were submitted as part of the QA/QC program. Duplicate and control sediment samples were submitted to evaluate the ability of the laboratory to reproduce analytical results. Control samples were also submitted to the analytical laboratory to evaluate their ability to quantify constituent concentrations in samples. A blank sample was submitted to the analytical laboratory to evaluate possible introduction of extraneous contamination to the sample by the analytical laboratory, whereas the wash water sample was submitted to evaluate possible contamination introduction to samples due to sampling protocol or inadequate sampling equipment decontamination.

The two duplicate sediment samples were selected from locations believed to contain differing levels of PCBs and metals. A duplicate sample of subsection sample FX-32 was selected as a lower concentration duplicate sediment sample, where as a duplicate sample of subsection sample DR-6 was submitted as a sample believed to contain moderate levels of PCBs.

A large volume of homogenized Long Island sediment currently maintained by the University of Connecticut which had previously been analyzed for lead, zinc and copper was selected as a suitable source for sediment control samples. These samples were designated as DR-56 and DR-60.

As a source of blank water, the University of Connecticut provided Balsam with distilled water from the University of Connecticut distillation unit which obtains its water from the Groton, Connecticut public water supply. Finally, as a field

control or wash water sample, Balsam collected a sample of wash water used as a final rinse for sediment sampling equipment while in the field.

Based on a review of analytical QA/QC program results summarized in Table 4, PCB sediment analytical data were judged to be reliable with the exception that low levels of PCB reported present in samples may be attributed to laboratory contamination. Zinc, copper, chromium and lead sediment analytical data were judged to be approximate in nature; in addition, low levels of these metals reported present in sediment samples may be attributed to laboratory contamination. Mercury analytical data were judged to be acceptable as reported.

## 5.0 SUMMARY

The results of this thin layer sediment sampling program indicate the presence of marked vertical stratification of both PCBs and heavy metals in New Bedford Harbor sediments. Significant data have been gathered regarding vertical stratification of these constituents in estuary sediments, as well as a better means to estimate actual surficial contaminant concentrations in estuary sediments utilizing sediment analytical data for larger sediment intervals (e.g. 0-6 inches or 0-12 inches).

**NEW BEDFORD HARBOR  
THIN LAYER SEDIMENT SAMPLING PROGRAM  
DECEMBER 1988 SAMPLING PROGRAM**

**1.0 INTRODUCTION**

In support of work currently being performed for Nutter, McClennen & Fish and the defense counsel to evaluate conditions and environmental mechanisms existing at the New Bedford Harbor Superfund site, W. Frank Bohlen, Ph.D., has prepared a proposal to better describe small-scale vertical distribution of sediment column PCBs and heavy metals. Balsam Environmental Consultants, Inc. (Balsam) reviewed this proposal and recommends proceeding with the scope of work presented with some modifications. Data obtained from this sampling program should provide much higher resolution information regarding small-scale vertical distribution of contaminants in New Bedford Harbor sediments.

Balsam has developed a sampling program to collect data allowing further assessment of small-scale vertical distribution of sediment column PCBs and heavy metals proposed by Dr. Bohlen. This sampling program is to be undertaken during the week of December 12, 1988.

To establish standard sampling practices prior to initiation of this sampling effort, sampling protocol have been developed for tasks proposed to be completed under this sampling program. These protocol are presented in the remainder of this document.

## D R A F T

**2.0 SAMPLE COLLECTION**

Sediment core samples will be obtained to provide data for the assessment of the occurrence of PCBs and heavy metals vertically in the sediment column of New Bedford Harbor. The metals to be evaluated are: mercury, chromium, copper, lead and zinc. A general protocol has been developed for the collection of sediment samples to provide data for this study.

Sediment core samples will be obtained using 3-inch-diameter Schedule 80 PVC core barrel samplers. The samplers were constructed with tapered cutting heads to allow sample collection with minimal sample disturbance and to increase sample recovery. The core barrel samplers will be installed on sampler extensions to allow pushing or driving of the sampler into marine sediments to a depth of up to 24 inches. After the sampler has been advanced 18 to 24 inches or to refusal, whichever occurs first, the sampler will be slowly withdrawn from the sediments and retrieved on board the sampling vessel.

Collection of sediment samples will be performed from boats equipped to conduct aquatic sediment sampling. Vessels will be equipped with all necessary equipment required for collection of sediment samples, pumps and apparatus to be used during equipment decontamination, appropriate safety gear for over-water sampling efforts, and electronic navigational equipment to permit accurate determination of sampling locations. Following the retrieval of a sediment sample, the sample will be frozen by placing it in a cooler with dry ice, or kept on ice to maintain samples near 4 degrees Centigrade. Samples not frozen will be kept in an upright position to maintain integrity. Determination of sample handling procedures will be based on field observations. In all cases, sample recovery will be measured to quantify the amount of sample recovered as compared to the depth to which the sampler was advanced.

## D R A F T

**3.0 SAMPLE HANDLING AND TRANSPORT**

This protocol describes methods for handling samples in the field and sample transport to laboratories for analyses. Sample handling protocol will be initiated immediately after the retrieval of sediment samples on board the sampling vessel.

Upon retrieval of a sediment sample from the harbor, the base of the core tube sampler will be capped to prevent loss of sediment from the open end of the sampler. After capping the base of the sampler, the sample tube will be washed with sea water to remove sediments adhering to the outside of the sample tube. This washing process will allow easier handling of the sample and minimize potential sample cross-contamination. Following initial cleaning of the sampling equipment, the water column above the sample will be drained to minimize disturbance of the sample surface. The core barrel sampler will be removed from the remainder of the sampling device to allow further processing of the sample. As previously discussed, sample recovery will be measured for all sediment core samples collected.

The sample will then be secured either in an upright position or frozen with both ends securely plugged or capped. Identification of the sample will occur by labeling the core barrel according to prescribed protocol. Samples to be frozen will be wrapped with packing material, enclosed in a plastic bag and placed in a cooler filled with dry ice to await further processing. Samples not frozen will be placed in plastic bags and packed with ice during storage and transportation. The sample bags will also be labeled according to prescribed protocol.

A minimum of three samples will be collected from two sampling locations to provide an adequate sample volume. The first location will be in an area

## D R A F T

reported to have some of the most elevated PCB sediment concentrations. The other sampling location will be in an area with above average sedimentation rates with moderately elevated PCB concentrations relative to the study area. Samples from each location will be collected as close as possible to each other to reduce variability.

Following collection and securing of all samples, samples will be transported to facilities at the University of Connecticut for further processing under the direct supervision of the sampling team. Here, the PVC core barrel sampler will be cut and split open exposing the core sample, or the sample will be extruded from the core barrel. The core sample will then be placed onto a pre-cleaned surface and sliced into thin layer subsamples. Subsamples will be sliced from the core sample using stainless steel utensils or wire. Sliced subsamples will then be placed on a flat, pre-cleaned surface and the exterior edge of the subsample which had been in contact with sidewalls of the barrel core sampler will be removed to reduce cross-contamination of the vertical profile. The remaining portion of the subsample will then be retained as a discrete subsample or interval of the vertical profile. This procedure will be performed for each sample to be subsectioned from the two sampling locations.

Subsamples of the vertical profile will be obtained in the following manner for the elevated PCB concentration sampling location:

Starting from the surface of the core sample, subsamples will be removed from the core sample in the following centimeter (cm) thicknesses:

0 - 1	
1 - 2	4 1-cm samples
2 - 3	
3 - 4

Following sectioning of subsamples and removal of perimeter surfaces, subsamples from each of the cores collected at a sampling station from the same vertical interval will be transferred to a pre-cleaned container or sample container to allow homogenization of each subsample interval and to obtain an adequate sample volume for chemical analysis. Following homogenization, the samples will be transferred to pre-cleaned glass, sample containers, if necessary, provided by the analytical laboratory to provide a sample amount of at least 25 grams. Tools utilized to section and homogenize samples will be acid washed and rinsed with distilled water prior to preparation of each subsection. The sample containers will then be labeled according to prescribed protocol and prepared for shipment. Samples will be stored on ice and maintained near 4 degrees Centigrade prior to and during transportation to the analytical laboratory. Cambridge Analytical Associates, Inc. has been selected as the

## D R A F T

analytical laboratory.

A uniform and comprehensive sample designation and management protocol has been developed for all samples which are to be processed by the analytical laboratory. To assist in keeping a record of sampling activities, a sampling log will be maintained and document, on a daily basis, the personnel involved in sampling activities, weather, general sampling activities, and a detailed description of samples collected each working day. In addition to a sampling log, sample chain-of-custody will be maintained from the time of sample collection through sample shipment to the analytical laboratory.

Immediately following completion of sample preparation, each sample will be labeled. Sample labeling will include assigning each sample a unique designation number including the project location, sample station, sample type and sample depth, as appropriate. In addition, sample collection time and sampling personnel will also be noted on the sample label.

Samples which are to be shipped to the outside analytical laboratory will be packaged in reinforced coolers. As previously discussed, samples will be shipped on ice to maintain these samples near 4 degrees Centigrade. At the time of sample shipment, Balsam personnel will transfer chain-of-custody to the receiving agent, place the completed chain-of-custody form in the shipping container, and seal the shipping container. Sample shipment will be conducted by overnight courier or personally by sampling team personnel.

## D R A F T

**4.0 QUALITY ASSURANCE/QUALITY CONTROL**

Quality Assurance/Quality Control (QA/QC) considerations have been incorporated throughout the development of this sampling program. Examples of QA/QC considerations included in the program are sample tracking and chain-of-custody documentation, as well as equipment decontamination procedures, discussed later in this document.

In addition to sampling protocol QA/QC efforts, further QA/QC efforts will be undertaken to evaluate performance of outside analytical laboratories. The analytical laboratory selected for sample analysis under this sampling program has been evaluated in terms of its current QA/QC practices. The laboratory selected to conduct PCB and metal chemical analyses on sediment samples has implemented pre-established QA/QC protocol including the analysis of blank samples, duplicate samples, spiked samples, and reference material samples.

To further address analytical laboratory accuracy and precision, Balsam has elected to submit additional samples to the analytical laboratory conducting PCB and metal analyses. These additional samples will include blank blind duplicate samples to allow assessment of analytical precision and reproducibility. Approximately 15 percent of all samples submitted to the analytical laboratory selected to perform PCB analyses on sediment samples will consist of QA/QC samples.

## D R A F T

**5.0 DECONTAMINATION PROTOCOL**

To minimize potential cross-contamination of sediment samples, sampling equipment utilized during the conduct of the sampling program will be decontaminated in accordance with the following protocol.

Prior to arrival at the site, all sampling equipment will be decontaminated using potable water and soap. Following cleaning, core barrel samplers will be packaged in plastic containers to prevent soiling during transport to the project site.

All sampling equipment will be decontaminated prior to collection of each sample using the following protocol. Samplers will be rinsed with potable water to wet equipment surfaces, followed by an acid wash. Equipment will then be rinsed with potable water. In addition to cleaning sampling equipment utilized during this sampling program, all personnel involved in the collection or handling of samples will be required to wash their gloves prior to the handling of each new sample.

Prior to sectioning core samples into subsamples at the University of Connecticut facilities, all utensils, surfaces and mixing bowls which may come in contact with samples will be decontaminated using potable water and soap. These utensils and surfaces will then receive a mild acid wash followed by a potable water rinse. To minimize potential cross-contamination of sediment subsamples, this procedure will be followed for any utensils or surfaces which are involved in sectioning subsamples following completion of a subsample and prior to initiating sectioning of a new subsample.

## D R A F T

**6.0 HEALTH AND SAFETY PROTOCOL**

Health and safety protocol have been developed based upon the reported presence of anthropogenic compounds in New Bedford Harbor sediments. Widely varying concentrations of Aroclors 1016, 1242 and 1254, as well as varying concentrations of numerous heavy metals, including copper, zinc, nickel, lead, chromium and mercury, and polycyclic aromatic hydrocarbons (PAHs) have been reported present in the sediment; low concentrations of other EPA Hazardous Substance List organic compounds have also been reported present in New Bedford Harbor sediments.

Based upon an evaluation of the types and concentrations of compounds present in New Bedford Harbor water and sediments, the primary routes of exposure are expected to be direct contact and ingestion. A review of the physical properties of compounds present in New Bedford Harbor media in combination with consideration of the concentrations of those compounds present does not indicate inhalation of vapors or contaminated particles to be a significant exposure pathway.

Based upon this expected exposure assessment, a modified EPA Level C health and safety protocol was selected for the conduct of this sampling program. This level of protection must be maintained by all personnel directly involved with sample collection. Protective equipment to be worn by sampling personnel is as follows:

- o **Outer Garment.** To provide protection against direct contact with contaminated sediments, rubber rainsuits will be worn by all sampling personnel. Rainsuits have been selected for use as compared to disposable coveralls due to their durability and superior ability to shed

## D R A F T

water and soil. A disposable inner Tyvek suit will also be worn beneath the rainsuit to provide additional protection during personnel decontamination and disrobing.

- o **Gloves.** Nitrile gloves will be worn by personnel involved with the collection and retrieval of sediment samples. Thin-layer surgical gloves may be worn by personnel documenting sediment sample collection or visually characterizing sediment samples.
- o **Boots.** Neoprene rubber boots will be worn by all sampling personnel.
- o **Eye Protection.** Goggles or approved safety glasses shall be worn by all personnel involved in the collection and handling of sediment samples.
- o **Respiratory Protection.** Dust masks shall be used by all personnel involved in the collection or processing of sediment samples. The sole purpose of dust mask use during this project is to prevent accidental ingestion of harbor sediments.

In addition to the use of protective clothing to maintain the health and safety of sampling personnel, rules have been developed regarding sampling personnel conduct for the period of this program. Eating, drinking, smoking, or chewing of tobacco or gum is prohibited during sample collection or processing activities. Restricted activities presented above may be performed only in designated areas after appropriate personnel decontamination has been conducted. Food intended to be consumed on board will be maintained in a designated clean area to prevent accidental contamination.

D R A F T

Running, jumping or horse play will not be allowed by any sampling personnel during sampling or sample processing activities. Personal flotation devices will be assigned to each sampling team member and will be utilized by that member during sampling efforts.

At the completion of a work day, each sampling team member will undertake thorough cleaning of reusable safety equipment and disposal of expendable safety equipment. Following this decontamination procedure, the individual will shower as soon as possible after returning to shore as a further precautionary measure.

TEST CODE CR I 8 NAME Chromium (Cr)-ICP

Method Reference: EPA. 1979. Methods for Chemical Analysis of Water and Wastes. EPA-600-4/79-020 (Revised March 1983). EPA/EMSL, Cincinnati, Ohio. Method 200.7-Inductively Coupled Plasma-Atomic Emission Spectrometric Method for Trace Element Analysis of Water and Wastes.

Method Description: Chromium is determined by inductively coupled argon plasma emission spectroscopy on a Jarrell-Ash Model 2000 sequential plasma spectrometer.

Quality Control Procedures: The instrument is calibrated using a blank and a 10 ppm standard. Accuracy of the working standards is verified by analysis of an independent EPA or NBS reference standard, and calibration is checked every 10 samples during the run. Procedural blanks are prepared with each batch of samples. Duplicates and matrix spikes are analyzed at a frequency of 10 %.

TEST CODE CU I 8 NAME Copper (Cu)-ICP

Method Reference: EPA. 1979. Methods for Chemical Analysis of Water and Wastes. EPA-600-4/79-020 (Revised March 1983). EPA/EMSL, Cincinnati, Ohio. Method 200.7-Inductively Coupled Plasma-Atomic Emission Spectrometric Method for Trace Element Analysis of Water and Wastes.

Method Description: Copper is determined by inductively coupled argon plasma emission spectroscopy on a Jarrell-Ash Model 2000 sequential plasma spectrometer.

REPORT  
Test Methodology

Work Order # 88-12-153  
Continued From Above

TEST CODE DIGSOL NAME Acid digestion-soil-SW846

Washington, DC.

Method Description: A 1.0-g aliquot of dried and ground sample is transferred to an acid-washed beaker. Following addition of 10 ml of 1:1 Instra-analyzed nitric acid, the sample is placed on a hot plate and refluxed for 10 min. without boiling. After cooling, a 5-ml portion of concentrated acid is added and the sample is refluxed for 30 min. After sample has cooled a second time 2-ml of deionized water is added, followed by 3 ml of 30 % hydrogen peroxide, and the sample is refluxed until digestion is complete (generally indicated by a yellow color). Additional hydrogen peroxide is added until no change in sample composition is observed (not more than 10-ml hydrogen peroxide). For furnace AAS determinations, the sample is diluted to 100 ml with distilled, deionized water so that the final acid concentration is 0.5 %. For flame AAS and ICP determinations, and for furnace determinations of Sb and Sn, the final dilution is performed with 1:1 HCl (5 ml/100 ml of solution). Insoluble material is removed by filtering or settling.

TEST CODE HG CVS NAME Mercury (Hg)-cold vapor

Method Reference: EPA. 1979. Methods for Chemical Analysis of Water and Wastes. EPA-600-4/79-020 (Revised March 1983). EPA/EMSL, Cincinnati, Ohio. Method 245.5-Mercury in Sediment (manual cold vapor technique).

Additional References: EPA. 1982. Test Methods for Evaluating Solid Waste. SW-846-Second edition. (Update No. 1-April 1984). EPA/Office of Solid Waste, Washington, DC. Method 7471-Mercury in Solid or Semi-solid Waste (manual cold-vapor technique).

Method Description: Mercury is determined in soils, sediments, bottom deposits, and sludges by digestion of sample in aqua regia for 2 min at 95 C, followed by oxidation with potassium permanganate and potassium persulfate. Mercury in the digested sample is then measured by cold vapor atomic absorption spectrophotometry on a SpectroProducts Hg-3 analyzer.

Quality Control Procedures: Instrumental calibration is performed by analyzing a blank and four or more working standards. Accuracy of working standards is verified by analysis of an independent check standard. With each batch of 10 samples and for each different matrix, one matrix spike and one duplicate analysis are performed.

TEST CODE PB\_I\_8 NAME Lead (Pb)-ICP

Method Reference: EPA. 1979. Methods for Chemical Analysis of Water and Wastes. EPA-600-4/79-020 (Revised March 1983). EPA/EMSL, Cincinnati, Ohio. Method 200.7-Inductively Coupled Plasma-Atomic Emission Spectrometric Method for Trace Element Analysis of Water and Wastes.

Method Description: Lead is determined by inductively coupled argon plasma emission spectroscopy on a Jarrell-Ash Model 2000 sequential plasma spectrometer.

Quality Control Procedures: The instrument is calibrated using a blank and a 10 ppm standard. Accuracy of the working standards is verified by analysis of an independent EPA or NBS reference standard, and calibration is checked every 10 samples during the run. Procedural blanks are prepared with each batch of samples. Duplicates and matrix spikes are analyzed at a frequency of 10 %.

TEST CODE PCB\_8 NAME PCBs-soil-SW846

Method Reference: U.S. EPA, 1982. Test Methods for Evaluating Solid Waste-Physical/Chemical Methods. Second Edition. SW-846. EPA/Office of Solid Waste, Washington, D.C. Method 8080, test method for organochlorine pesticides and PCBs.

Method Description: The analytes in a solid sample are isolated and concentrated by solvent extraction. The extract is injected into a gas chromatograph (GC) where the analytes are separated and detected with an electron capture detector (ECD).

Quality Control Procedures: Instrument response is calibrated every twelve hours using EPA traceable standard reference solutions. Analytes are quantified using the external standard method. Surrogate standard compounds are added to every sample to monitor method performance. Additional quality control includes the analysis of replicates, matrix spikes, duplicate matrix spikes, and blanks.

TEST CODE ZN\_I\_8 NAME Zinc (Zn)-ICP

Method Reference: EPA. 1979. Methods for Chemical Analysis of Water and Wastes. EPA-600-4/79-020 (Revised March 1983). EPA/EMSL, Cincinnati, Ohio. Method 200.7-Inductively Coupled Plasma-Atomic Emission Spectrometric Method for Trace Element Analysis of Water and Wastes.

TEST CODE CR\_I\_S NAME Chromium (Cr)-ICP

Method Reference: EPA. 1979. Methods for Chemical Analysis of Water and Wastes. EPA-600-4/79-020 (Revised March 1983). EPA/EMSL, Cincinnati, Ohio. Method 200.7-Inductively Coupled Plasma-Atomic Emission Spectrometric Method for Trace Element Analysis of Water and Wastes.

Method Description: Chromium is determined by inductively coupled argon plasma emission spectroscopy on a Jarrell-Ash Model 2000 sequential plasma spectrometer.

Quality Control Procedures: The instrument is calibrated using a blank and a 10 ppm standard. Accuracy of the working standards is verified by analysis of an independent EPA or NBS reference standard, and calibration is checked every 10 samples during the run. Procedural blanks are prepared with each batch of samples. Duplicates and matrix spikes are analyzed at a frequency of 10 %.

TEST CODE CU\_I\_S NAME Copper (Cu)-ICP

Method Reference: EPA. 1979. Methods for Chemical Analysis of Water and Wastes. EPA-600-4/79-020 (Revised March 1983). EPA/EMSL, Cincinnati, Ohio. Method 200.7-Inductively Coupled Plasma-Atomic Emission Spectrometric Method for Trace Element Analysis of Water and Wastes.

Method Description: Copper is determined by inductively coupled argon plasma emission spectroscopy on a Jarrell-Ash Model 2000 sequential plasma spectrometer.

Quality Control Procedures: The instrument is calibrated using a blank and a 10 ppm standard. Accuracy of the working standards is verified by analysis of an independent EPA or NBS reference standard, and calibration is checked every 10 samples during the run. Procedural blanks are prepared with each batch of samples. Duplicates and matrix spikes are analyzed at a frequency of 10 %.

TEST CODE DIGSOL NAME Acid digestion-soil-SW846

Method Description: EPA. 1979. Methods for Chemical Analysis of Water and Wastes. EPA-600-4/79-020 (Revised March 1983). EPA/EMSL, Cincinnati, Ohio. Section 4.1.3.

Additional references: EPA. 1982. Test Methods for Evaluating Solid Waste-Physical/Chemical Methods. SW-846. EPA/Office of Solid Waste,

Continued From Above

TEST CODE DIGSOL NAME Acid digestion-soil-SW846

Washington, DC.

Method Description: A 1.0-g aliquot of dried and ground sample is transferred to an acid-washed beaker. Following addition of 10 ml of 1:1 Instra-analyzed nitric acid, the sample is placed on a hot plate and refluxed for 10 min. without boiling. After cooling, a 5-ml portion of concentrated acid is added and the sample is refluxed for 30 min. After sample has cooled a second time 2-ml of deionized water is added, followed by 3 ml of 30 % hydrogen peroxide, and the sample is refluxed until digestion is complete (generally indicated by a yellow color). Additional hydrogen peroxide is added until no change in sample composition is observed (not more than 10-ml hydrogen peroxide). For furnace AAS determinations, the sample is diluted to 100 ml with distilled, deionized water so that the final acid concentration is 0.5 %. For flame AAS and ICP determinations, and for furnace determinations of Sb and Sn, the final dilution is performed with 1:1 HCl (5 ml/100 ml of solution). Insoluble material is removed by filtering or settling.

TEST CODE HG CVS NAME Mercury (Hg)-cold vapor

Method Reference: EPA. 1979. Methods for Chemical Analysis of Water and Wastes. EPA-600-4/79-020 (Revised March 1983). EPA/EMSL, Cincinnati, Ohio. Method 245.5-Mercury in Sediment (manual cold vapor technique).

Additional References: EPA. 1982. Test Methods for Evaluating Solid Waste. SW-846-Second edition. (Update No. 1-April 1984). EPA/Office of Solid Waste, Washington, DC. Method 7471-Mercury in Solid or Semi-solid Waste (manual cold-vapor technique).

Method Description: Mercury is determined in soils, sediments, bottom deposits, and sludges by digestion of sample in aqua regia for 2 min at 95 C, followed by oxidation with potassium permanganate and potassium persulfate. Mercury in the digested sample is then measured by cold vapor atomic absorption spectrophotometry on a SpectroProducts Hg-3 analyzer.

Quality Control Procedures: Instrumental calibration is performed by analyzing a blank and four or more working standards. Accuracy of working standards is verified by analysis of an independent check standard. With each batch of 10 samples and for each different matrix, one matrix spike and one duplicate analysis are performed.

TEST CODE PB\_I\_S NAME Lead (Pb)-ICP

Method Reference: EPA. 1979. Methods for Chemical Analysis of Water and Wastes. EPA-600-4/79-020 (Revised March 1983). EPA/EMSL, Cincinnati, Ohio. Method 200.7-Inductively Coupled Plasma-Atomic Emission Spectrometric Method for Trace Element Analysis of Water and Wastes.

Method Description: Lead is determined by inductively coupled argon plasma emission spectroscopy on a Jarrell-Ash Model 2000 sequential plasma spectrometer.

Quality Control Procedures: The instrument is calibrated using a blank and a 10 ppm standard. Accuracy of the working standards is verified by analysis of an independent EPA or NBS reference standard, and calibration is checked every 10 samples during the run. Procedural blanks are prepared with each batch of samples. Duplicates and matrix spikes are analyzed at a frequency of 10 %.

TEST CODE PCB\_S NAME PCBs-soil-SW846

Method Reference: U.S. EPA, 1982. Test Methods for Evaluating Solid Waste-Physical/Chemical Methods. Second Edition. SW-846. EPA/Office of Solid Waste, Washington, D.C. Method 8080, test method for organochlorine pesticides and PCBs.

Method Description: The analytes in a solid sample are isolated and concentrated by solvent extraction. The extract is injected into a gas chromatograph (GC) where the analytes are separated and detected with an electron capture detector (ECD).

Quality Control Procedures: Instrument response is calibrated every twelve hours using EPA traceable standard reference solutions. Analytes are quantified using the external standard method. Surrogate standard compounds are added to every sample to monitor method performance. Additional quality control includes the analysis of replicates, matrix spikes, duplicate matrix spikes, and blanks.

TEST CODE ZN\_I\_S NAME Zinc (Zn)-ICP

Method Reference: EPA. 1979. Methods for Chemical Analysis of Water and Wastes. EPA-600-4/79-020 (Revised March 1983). EPA/EMSL, Cincinnati, Ohio. Method 200.7-Inductively Coupled Plasma-Atomic Emission Spectrometric Method for Trace Element Analysis of Water and Wastes.

TEST CODE ZN I S NAME Zinc (Zn)-ICP

Method Description: Zinc is determined by inductively coupled argon plasma emission spectroscopy on a Jarrell-Ash Model 2000 sequential plasma spectrometer.

Quality Control Procedures: The instrument is calibrated using a blank and a 10 ppm standard. Accuracy of the working standards is verified by analysis of an independent EPA or NBS reference standard, and calibration is checked every 10 samples during the run. Procedural blanks are prepared with each batch of samples. Duplicates and matrix spikes are analyzed at a frequency of 10 %.

TEST CODE CR\_I\_A NAME Chromium (Cr)-ICP

Method Reference: EPA. 1979. Methods for Chemical Analysis of Water and Wastes. EPA-600-4/79-020 (Revised March 1983). EPA/EMSL, Cincinnati, Ohio. Method 200.7-Inductively Coupled Plasma-Atomic Emission Spectrometric Method for Trace Element Analysis of Water and Wastes.

Method Description: Chromium is determined by inductively coupled argon plasma emission spectroscopy on a Jarrell-Ash Model 2000 sequential plasma spectrometer.

Quality Control Procedures: The instrument is calibrated using a blank and a 10 ppm standard. Accuracy of the working standards is verified by analysis of an independent EPA or NBS reference standard, and calibration is checked every 10 samples during the run. Procedural blanks are prepared with each batch of samples. Duplicates and matrix spikes are analyzed at a frequency of 10 %.

TEST CODE CR\_I\_S NAME Chromium (Cr)-ICP

Method Reference: EPA. 1979. Methods for Chemical Analysis of Water and Wastes. EPA-600-4/79-020 (Revised March 1983). EPA/EMSL, Cincinnati, Ohio. Method 200.7-Inductively Coupled Plasma-Atomic Emission Spectrometric Method for Trace Element Analysis of Water and Wastes.

Method Description: Chromium is determined by inductively coupled argon plasma emission spectroscopy on a Jarrell-Ash Model 2000 sequential plasma spectrometer.

Quality Control Procedures: The instrument is calibrated using a blank and a 10 ppm standard. Accuracy of the working standards is verified by analysis of an independent EPA or NBS reference standard, and calibration is checked every 10 samples during the run. Procedural blanks are prepared with each batch of samples. Duplicates and matrix spikes are analyzed at a frequency of 10 %.

TEST CODE CU\_I\_A NAME Copper (Cu)-ICP

Method Reference: EPA. 1979. Methods for Chemical Analysis of Water and Wastes. EPA-600-4/79-020 (Revised March 1983). EPA/EMSL, Cincinnati, Ohio. Method 200.7-Inductively Coupled Plasma-Atomic Emission Spectrometric Method for Trace Element Analysis of Water and Wastes.

TEST CODE CU\_I\_A NAME Copper (Cu)-ICP

Method Description: Copper is determined by inductively coupled argon plasma emission spectroscopy on a Jarrell-Ash Model 2000 sequential plasma spectrometer or Jarrell-Ash Model 975 simultaneous plasma spectrometer.

Quality Control Procedures: The instrument is calibrated using a blank and a 10 ppm standard. Accuracy of the working standards is verified by analysis of an independent EPA or NBS reference standard, and calibration is checked every 10 samples during the run. Procedural blanks are prepared with each batch of samples. Duplicates and matrix spikes are analyzed at a frequency of 10 %.

TEST CODE CU\_I\_S NAME Copper (Cu)-ICP

Method Reference: EPA. 1979. Methods for Chemical Analysis of Water and Wastes. EPA-600-4/79-020 (Revised March 1983). EPA/EMSL, Cincinnati, Ohio. Method 200.7-Inductively Coupled Plasma-Atomic Emission Spectrometric Method for Trace Element Analysis of Water and Wastes.

Method Description: Copper is determined by inductively coupled argon plasma emission spectroscopy on a Jarrell-Ash Model 2000 sequential plasma spectrometer.

Quality Control Procedures: The instrument is calibrated using a blank and a 10 ppm standard. Accuracy of the working standards is verified by analysis of an independent EPA or NBS reference standard, and calibration is checked every 10 samples during the run. Procedural blanks are prepared with each batch of samples. Duplicates and matrix spikes are analyzed at a frequency of 10 %.

TEST CODE DIGSOL NAME Acid digestion-soil-SW846

Method Description: EPA. 1979. Methods for Chemical Analysis of Water and Wastes. EPA-600-4/79-020 (Revised March 1983). EPA/EMSL, Cincinnati, Ohio. Section 4.1.3.

Additional references: EPA. 1982. Test Methods for Evaluating Solid Waste-Physical/Chemical Methods. SW-846. EPA/Office of Solid Waste, Washington, DC.

Method Description: A 1.0-g aliquot of dried and ground sample is transferred to an acid-washed beaker. Following addition of 10 ml of 1:1 Instra-analyzed nitric acid, the sample is placed on a hot plate and refluxed for 10 min.

TEST CODE DIGSOL NAME Acid digestion-soil-SW846

without boiling. After cooling, a 5-ml portion of concentrated acid is added and the sample is refluxed for 30 min. After sample has cooled a second time 2-ml of deionized water is added, followed by 3 ml of 30 % hydrogen peroxide, and the sample is refluxed until digestion is complete (generally indicated by a yellow color). Additional hydrogen peroxide is added until no change in sample composition is observed (not more than 10-ml hydrogen peroxide). For furnace AAS determinations, the sample is diluted to 100 ml with distilled, deionized water so that the final acid concentration is 0.5 %. For flame AAS and ICP determinations, and for furnace determinations of Sb and Sn, the final dilution is performed with 1:1 HCl (5 ml/100 ml of solution). Insoluble material is removed by filtering or settling.

TEST CODE DIG\_AQ NAME Acid digestion-aqueous-EPA

Method Description: EPA. 1979. Methods for Chemical Analysis of Water and Wastes. EPA-600-4/79-020 (Revised March 1983). EPA/EMSL, Cincinnati, Ohio. Section 4.1.3.

Additional references: EPA. 1982. Test Methods for Evaluating Solid Waste-Physical/Chemical Methods. SW-846. EPA/Office of Solid Waste, Washington, DC.

Method Description: A 100-ml aliquot of sample is transferred to an acid-washed beaker. Following addition of 3 ml of concentrated Instra-analyzed nitric acid, the sample is placed on a hot plate and evaporated to near-dryness without boiling. After cooling, another 3-ml portion of acid is added, followed by 2 ml of 30 % hydrogen peroxide, and the sample is refluxed until digestion is complete (generally indicated by a yellow color). Additional acid is added until no change in sample composition is observed. The sample is again taken to near-dryness. For furnace AAS determinations, the sample is diluted to 100 ml with distilled, deionized water so that the final acid concentration is 0.5 %. For flame AAS and ICP determinations, and for furnace determinations of Sb and Sn, the final dilution is performed with 1:1 HCl (5 ml/100 ml of solution). Insoluble material is removed by filtering or settling.

TEST CODE HG\_CVA NAME Mercury (Hg)-cold vapor

Method Reference: EPA. 1979. Methods for Chemical Analysis of Water and Wastes. EPA-600-4/79-020 (Revised March 1983). EPA/EMSL, Cincinnati, Ohio. Method 245.1-Mercury (Manual Cold Vapor Technique).

Additional References: EPA. 1982. Test Methods for Evaluating Solid Waste. SW-846-Second edition. (Update No. 1-April 1984). EPA/Office of Solid Waste, Washington, DC. Method 7470-Mercury (Manual Cold-Vapor Technique).

Method Description: Mercury is determined in drinking, surface and saline waters, as well as domestic and industrial wastes by digestion of sample in sulfuric and nitric acids, followed by oxidation with potassium permanganate and potassium persulfate. Mercury in the digested sample is then measured by cold vapor atomic absorption spectrophotometry on a SpectroProducts Hg-3 analyzer.

Quality Control Procedures: Instrumental calibration is performed by analyzing a blank and four or more working standards. Accuracy of the working standards is verified by analysis of an independent EPA or NBS reference standard, and calibration is checked every 10 samples during the run. Procedural blanks are prepared with each batch of samples. Matrix spikes and duplicates are analyzed at a frequency of 10 %.

TEST CODE HG\_CVS NAME Mercury (Hg)-cold vapor

Method Reference: EPA. 1979. Methods for Chemical Analysis of Water and Wastes. EPA-600-4/79-020 (Revised March 1983). EPA/EMSL, Cincinnati, Ohio. Method 245.5-Mercury in Sediment (manual cold vapor technique).

Additional References: EPA. 1982. Test Methods for Evaluating Solid Waste. SW-846-Second edition. (Update No. 1-April 1984). EPA/Office of Solid Waste, Washington, DC. Method 7471-Mercury in Solid or Semi-solid Waste (manual cold-vapor technique).

Method Description: Mercury is determined in soils, sediments, bottom deposits, and sludges by digestion of sample in aqua regia for 2 min at 95 C, followed by oxidation with potassium permanganate and potassium persulfate. Mercury in the digested sample is then measured by cold vapor atomic absorption spectrophotometry on a SpectroProducts Hg-3 analyzer.

Quality Control Procedures: Instrumental calibration is performed by analyzing a blank and four or more working standards. Accuracy of working standards is verified by analysis of an independent check standard. With each batch of 10 samples and for each different matrix, one matrix spike and one duplicate analysis are performed.

Test Methodology

Work Order # 88-12-195

TEST CODE PB I A NAME Lead (Pb)-ICP

Method Reference: EPA. 1979. Methods for Chemical Analysis of Water and Wastes. EPA-600-4/79-020 (Revised March 1983). EPA/EMSL, Cincinnati, Ohio. Method 200.7-Inductively Coupled Plasma-Atomic Emission Spectrometric Method for Trace Element Analysis of Water and Wastes.

Method Description: Lead is determined by inductively coupled argon plasma emission spectroscopy on a Jarrell-Ash Model 2000 sequential plasma spectrometer.

Quality Control Procedures: The instrument is calibrated using a blank and a 10 ppm standard. Accuracy of the working standards is verified by analysis of an independent EPA or NBS reference standard, and calibration is checked every 10 samples during the run. Procedural blanks are prepared with each batch of samples. Duplicates and matrix spikes are analyzed at a frequency of 10 %.

TEST CODE PB I S NAME Lead (Pb)-ICP

Method Reference: EPA. 1979. Methods for Chemical Analysis of Water and Wastes. EPA-600-4/79-020 (Revised March 1983). EPA/EMSL, Cincinnati, Ohio. Method 200.7-Inductively Coupled Plasma-Atomic Emission Spectrometric Method for Trace Element Analysis of Water and Wastes.

Method Description: Lead is determined by inductively coupled argon plasma emission spectroscopy on a Jarrell-Ash Model 2000 sequential plasma spectrometer.

Quality Control Procedures: The instrument is calibrated using a blank and a 10 ppm standard. Accuracy of the working standards is verified by analysis of an independent EPA or NBS reference standard, and calibration is checked every 10 samples during the run. Procedural blanks are prepared with each batch of samples. Duplicates and matrix spikes are analyzed at a frequency of 10 %.

TEST CODE PCB A NAME PCBs-aqueous-EPA 608

Method Reference: U.S. EPA, 1984. Methods for Organic Analysis of Municipal and Industrial Wastewater. Appendix A. 40CFR Part 136. Federal Register, Vol. 49, No. 209. Method 608, test method for Organochlorine Pesticides and PCBs.

Method Description: The analytes in an aqueous sample are isolated and

TEST CODE PCB\_A NAME PCBs-aqueous-EPA 608

concentrated by solvent extraction. The extract is injected into into a gas chromatograph (GC) where the analytes are separated and detected with an electron capture detector (ECD).

Quality Control Procedures: Instrument response is calibrated every twelve hours using EPA traceable standard reference solutions. Analytes are quantified using the external standard method. Surrogate standard compounds are added to every sample to monitor method performance. Additional quality control includes the analysis of replicates, matrix spikes, duplicate matrix spikes, and blanks.

TEST CODE PCB\_S NAME PCBs-soil-SW846

Method Reference: U.S. EPA, 1982. Test Methods for Evaluating Solid Waste-Physical/Chemical Methods. Second Edition. SW-846. EPA/Office of Solid Waste, Washington, D.C. Method 8080, test method for organochlorine pesticides and PCBs.

Method Description: The analytes in a solid sample are isolated and concentrated by solvent extraction. The extract is injected into into a gas chromatograph (GC) where the analytes are separated and detected with an electron capture detector (ECD).

Quality Control Procedures: Instrument response is calibrated every twelve hours using EPA traceable standard reference solutions. Analytes are quantified using the external standard method. Surrogate standard compounds are added to every sample to monitor method performance. Additional quality control includes the analysis of replicates, matrix spikes, duplicate matrix spikes, and blanks.

TEST CODE ZN\_I\_A NAME Zinc (Zn)-ICP

Method Reference: EPA. 1979. Methods for Chemical Analysis of Water and Wastes. EPA-600-4/79-020 (Revised March 1983). EPA/EMSL, Cincinnati, Ohio. Method 200.7-Inductively Coupled Plasma-Atomic Emission Spectrometric Method for Trace Element Analysis of Water and Wastes.

Method Description: Zinc is determined by inductively coupled argon plasma emission spectroscopy on a Jarrell-Ash Model 2000 sequential plasma spectrometer.
