

Key Health Effects Information in Recent NAAQS Reviews

Beth M. Hassett-Sipple
Deirdre Murphy
US EPA/OAQPS

National Ambient Air Monitoring
Conference
November 3, 2009

Overview

- Type of health effects data considered in reviews of primary National Ambient Air Quality Standards (NAAQS)
- Recent/ongoing NAAQS reviews
 - Particulate matter (PM)
 - Nitrogen Dioxide (NO₂)
 - Lead (Pb)

Types of Health Effects Evidence

- Epidemiological studies
 - Health outcomes associated with normal exposures to ambient mix of air pollutants (e.g., PM)
 - Health outcomes associated with levels of internal marker (e.g., Pb)
- Controlled human exposure studies
 - Human responses to known exposures
- Toxicological studies
 - Animal studies, short- and long-term exposures
- *In vitro* studies

NAAQS Assessments . . .

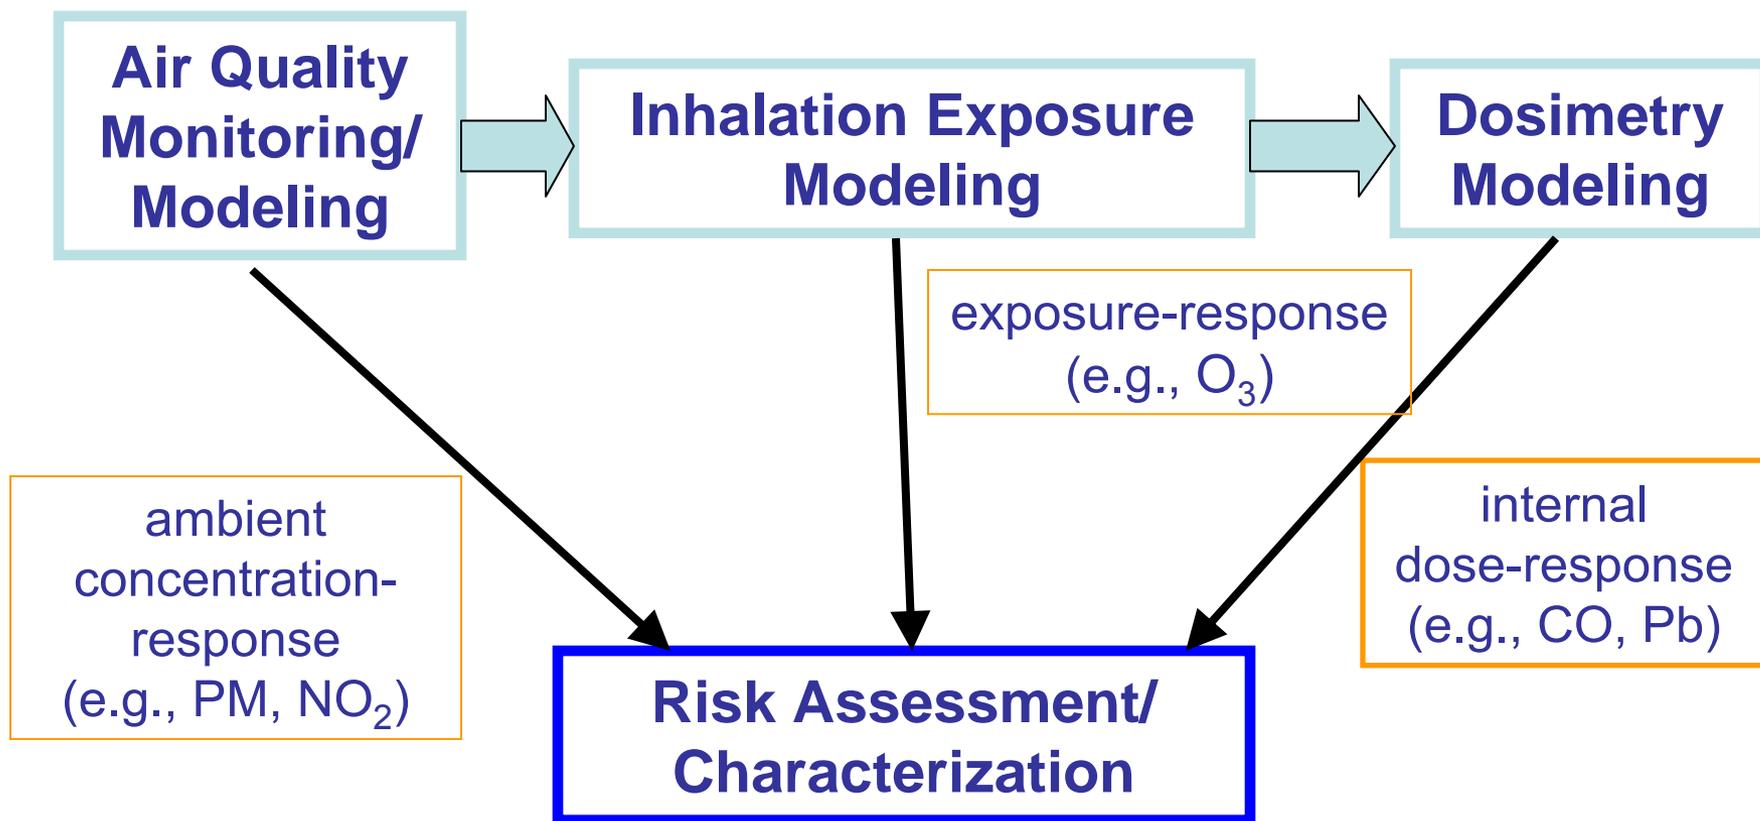

Hazard and “Dose”

- Hazard characterization – weight-of-evidence approach, using all relevant information
 - Patterns of exposure
 - Nature and severity of effects
 - Nature and size of at-risk populations
 - Kind and degree of uncertainties
 - Consistency/coherence across all types of available evidence
- “Dose”-response evaluations – based on nature of available evidence from human studies, generally with no discernable thresholds (effects observed at current ambient concentrations)

Causality Determinations

- Integrated Science Assessment (ISA) employs a 5-level hierarchy to characterize causality judgments
 - Sufficient to infer a causal relationship
 - Sufficient to infer a likely causal relationship
 - Suggestive, but not sufficient to infer a causal relationship
 - Inadequate to infer the presence or absence of a causal relationship
 - Suggestive of no causal relationship

Type of Health Effects Evidence Affects How Characterize Risk

NAAQS Assessments . . .

Exposure

- Inhalation exposure assessment
 - Air quality monitoring/modeling and simulations of “just attaining” alternative standards
 - Pollutant concentrations within relevant microenvironments (home, yard, car, office)
 - Amount of time in different microenvironments and level of exertion (time-activity and breathing rate data)
 - Population demographics (census data, commuting patterns)
 - Probabilistic assessment (including uncertainty, variability, sensitivity analyses)
- Provides ability to identify and characterize exposure distributions for at-risk groups

NAAQS Assessments . . .

Risk Characterization

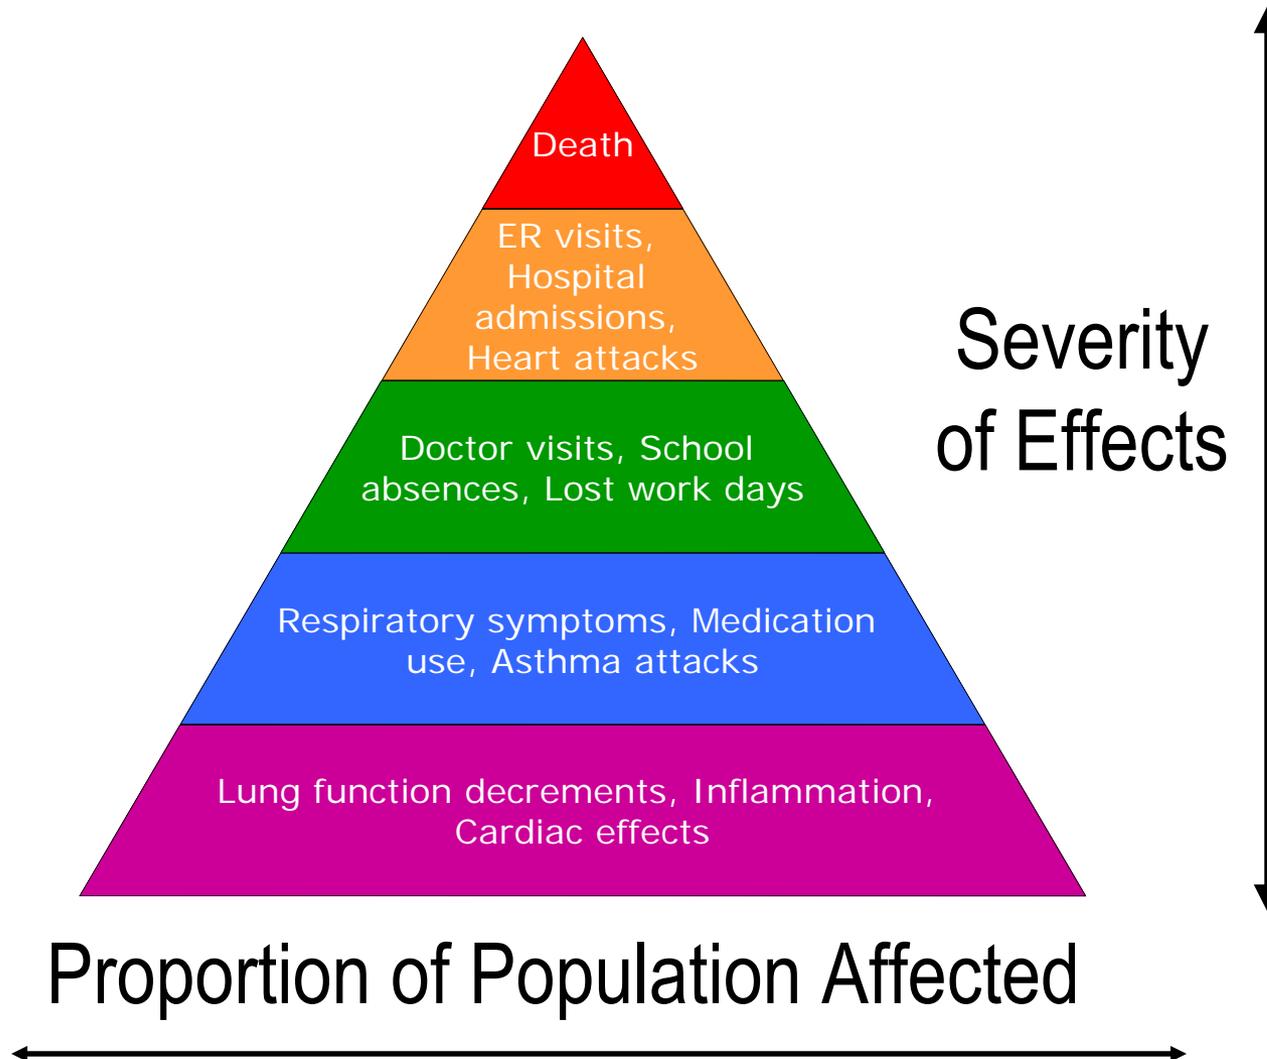

- Risk characterization – qualitative and quantitative approaches
 - Integration of evidence on health effects associated with short- or long-term exposures (strengths, weaknesses, uncertainties)
 - Identification of and focus on at-risk groups
 - Expert judgments on adversity of effects (severity, duration, frequency)
 - Qualitative and quantitative assessments of population exposures of concern and/or risks to public health
- Risk communication – put risk characterization into public health policy context

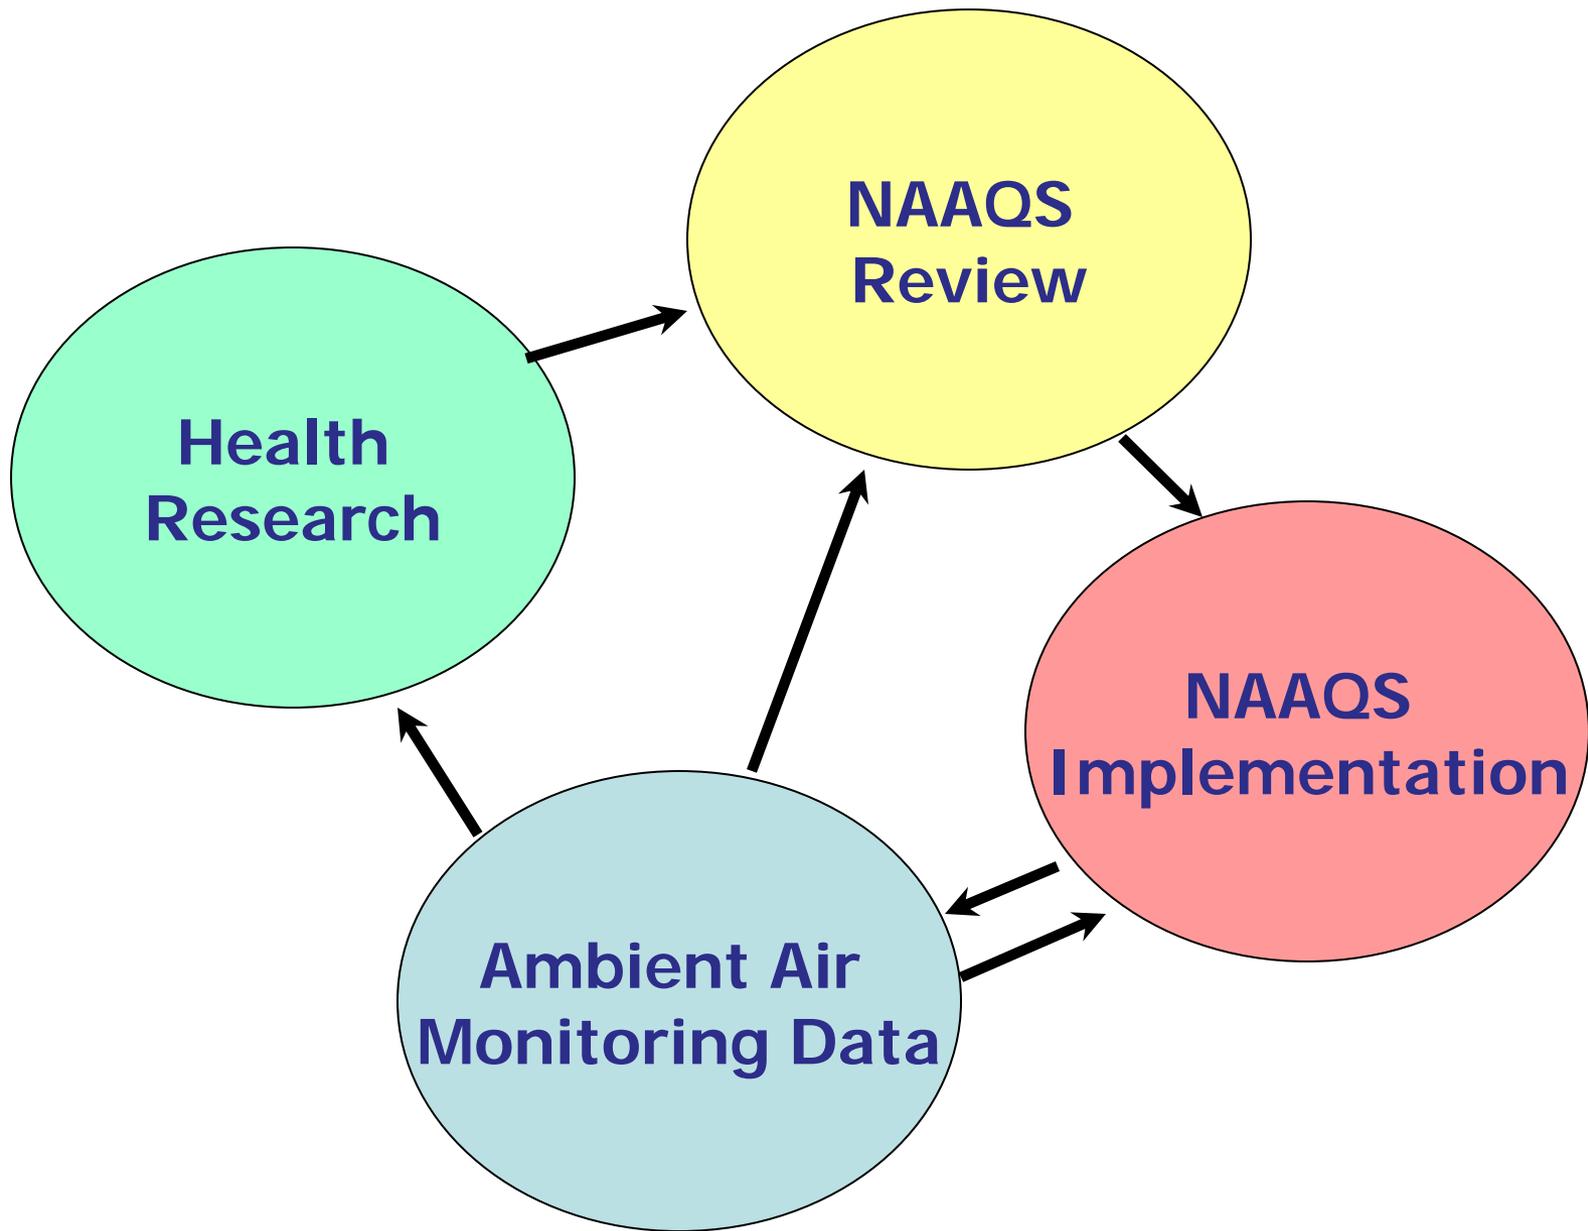

Some populations are at increased risk ...

- People with heart or lung disease
- Older adults
 - Greater prevalence of heart and lung disease
- Children
 - More likely to be active
 - Breathe more air per pound
 - Bodies still developing
 - Conditions making some populations more vulnerable
 - Low SES (e.g., less access to health care)
 - Residence near roadways
- Others?

Risk Characterization: Understanding Broader Public Health Impacts

Particulate Matter (PM)

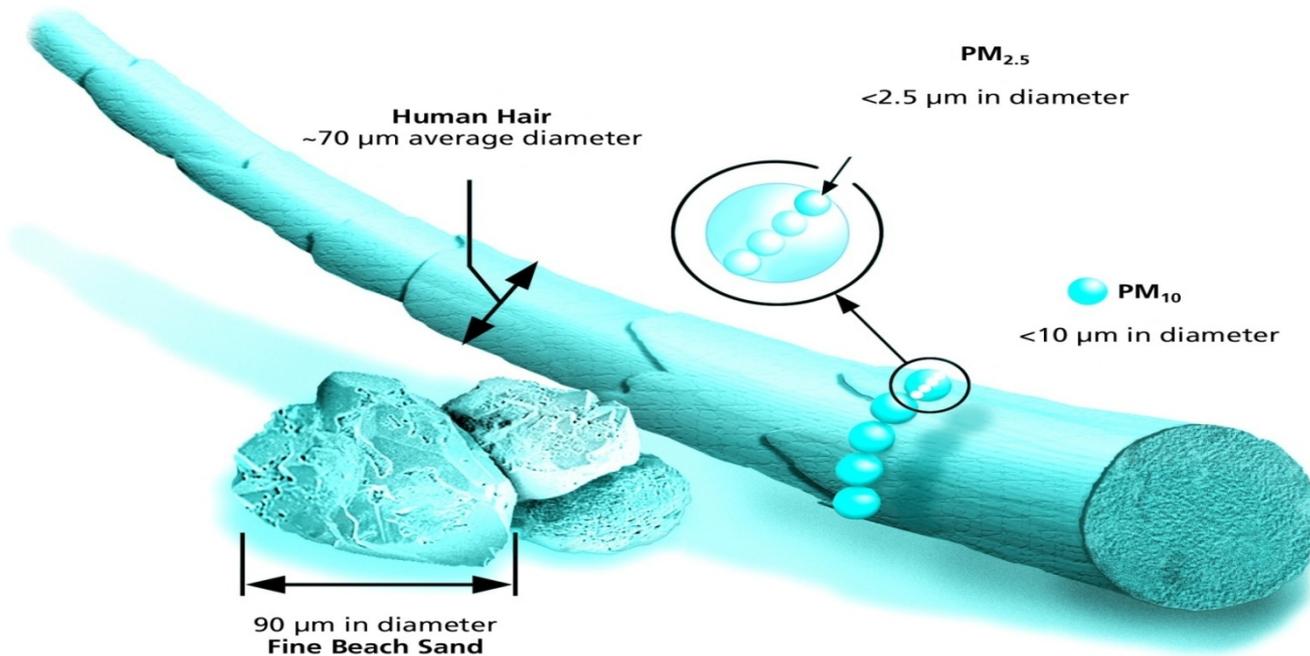

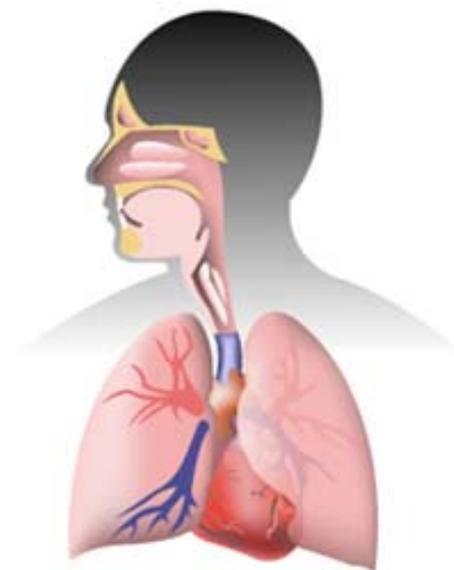

Image courtesy of EPA, Office of Research and Development

Particulate Matter

- Larger particles ($> PM_{10}$) deposit in the upper respiratory tract →
- Smaller, inhalable particles ($\leq PM_{10}$) penetrate deep into the lungs →

- Both coarse particulate matter and fine particulate matter can penetrate to lower regions of the lung
- Deposited particles may accumulate, react, be cleared or absorbed

Final Rule	Indicator	Ave. Time	Level	Form
1971	TSP - Total Suspended Particles ($\leq 25\text{-}45\ \mu\text{m}$)	24-hour	260 $\mu\text{g}/\text{m}^3$ (primary) 150 $\mu\text{g}/\text{m}^3$ (secondary)	Not to be exceeded more than once per year
		Annual	75 $\mu\text{g}/\text{m}^3$ (primary)	Annual average
1987	PM₁₀	24-hour	150 $\mu\text{g}/\text{m}^3$*	Not to be exceeded more than once per year
		Annual	50 $\mu\text{g}/\text{m}^3$	Annual average
1997	PM_{2.5}	24-hour	65 $\mu\text{g}/\text{m}^3$	98 th percentile
		Annual	15 $\mu\text{g}/\text{m}^3$	Annual arithmetic mean, ave. over 3 years
	PM₁₀	24-hour	150 $\mu\text{g}/\text{m}^3$	Initially promulgated 99 th percentile form; when 1997 standards were vacated, form of 1987 standards remained in place (not to be exceeded more than once per year on ave. over a three year period)
		Annual	50 $\mu\text{g}/\text{m}^3$	Annual arithmetic mean, ave. over 3 years
2006	PM_{2.5}	24-hour	35 $\mu\text{g}/\text{m}^3$	98 th percentile, ave. over 3 years
		Annual	15 $\mu\text{g}/\text{m}^3$	Annual arithmetic mean, ave. over 3 years
	PM₁₀	24-hour	150 $\mu\text{g}/\text{m}^3$	Not to be exceeded more than once per year on ave. over a 3 year period

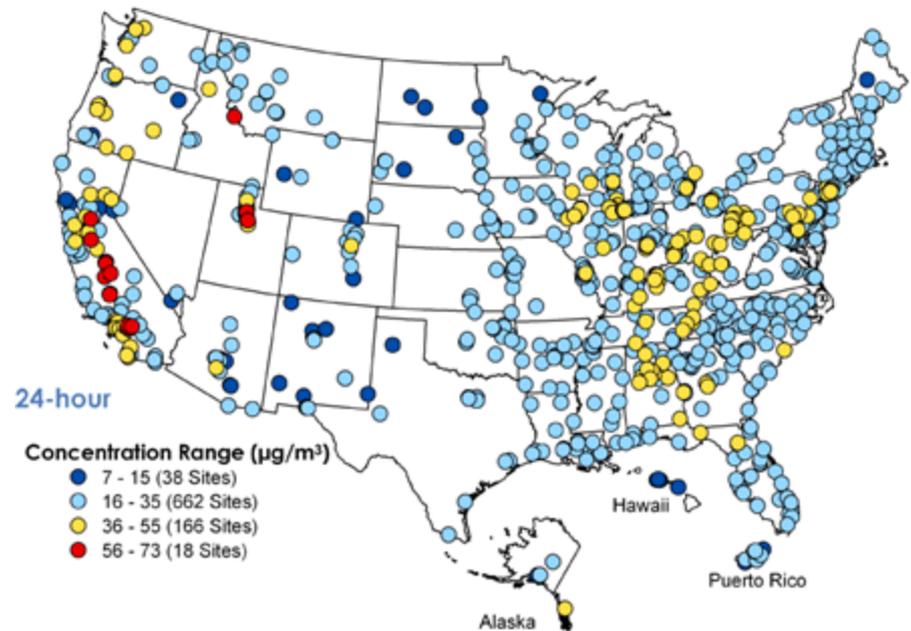

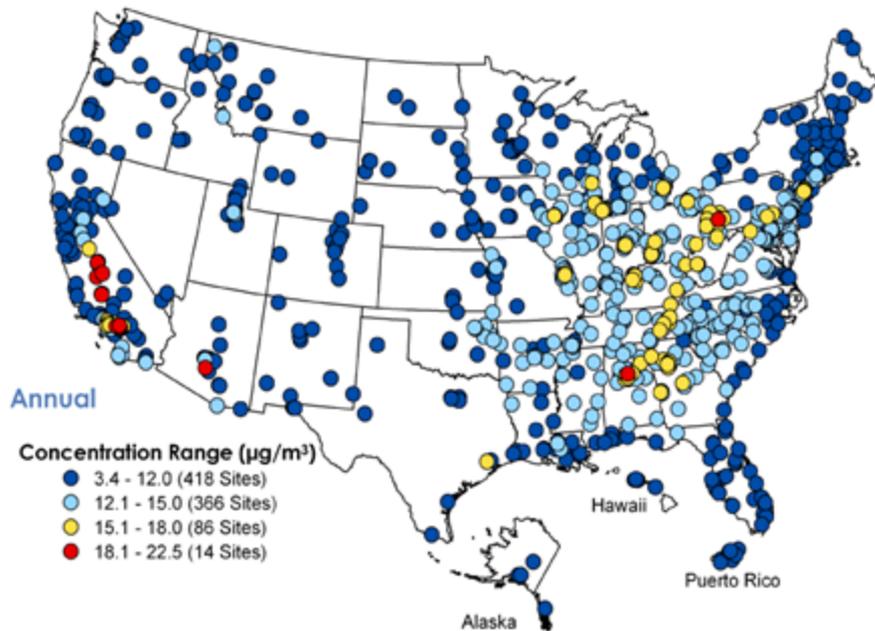

Remand of 2006 PM NAAQS: *Overview*

- D.C. Circuit Court issued decision on February 24, 2009
- PM_{2.5} standards:
 - Remanded primary annual PM_{2.5} standard (retained at 15 µg/m³) and secondary PM_{2.5} standards (set identical to primary standards)
 - Primary 24-hour PM_{2.5} standard (revised to 35 µg/m³) not challenged
- PM₁₀ standards:
 - Upheld decisions to retain 24-hour PM₁₀ standard and revoke annual PM₁₀ standard
 - Based on finding EPA reasonably explained decision to regulate all coarse PM (including nonurban PM) and use of PM₁₀ as indicator for coarse PM

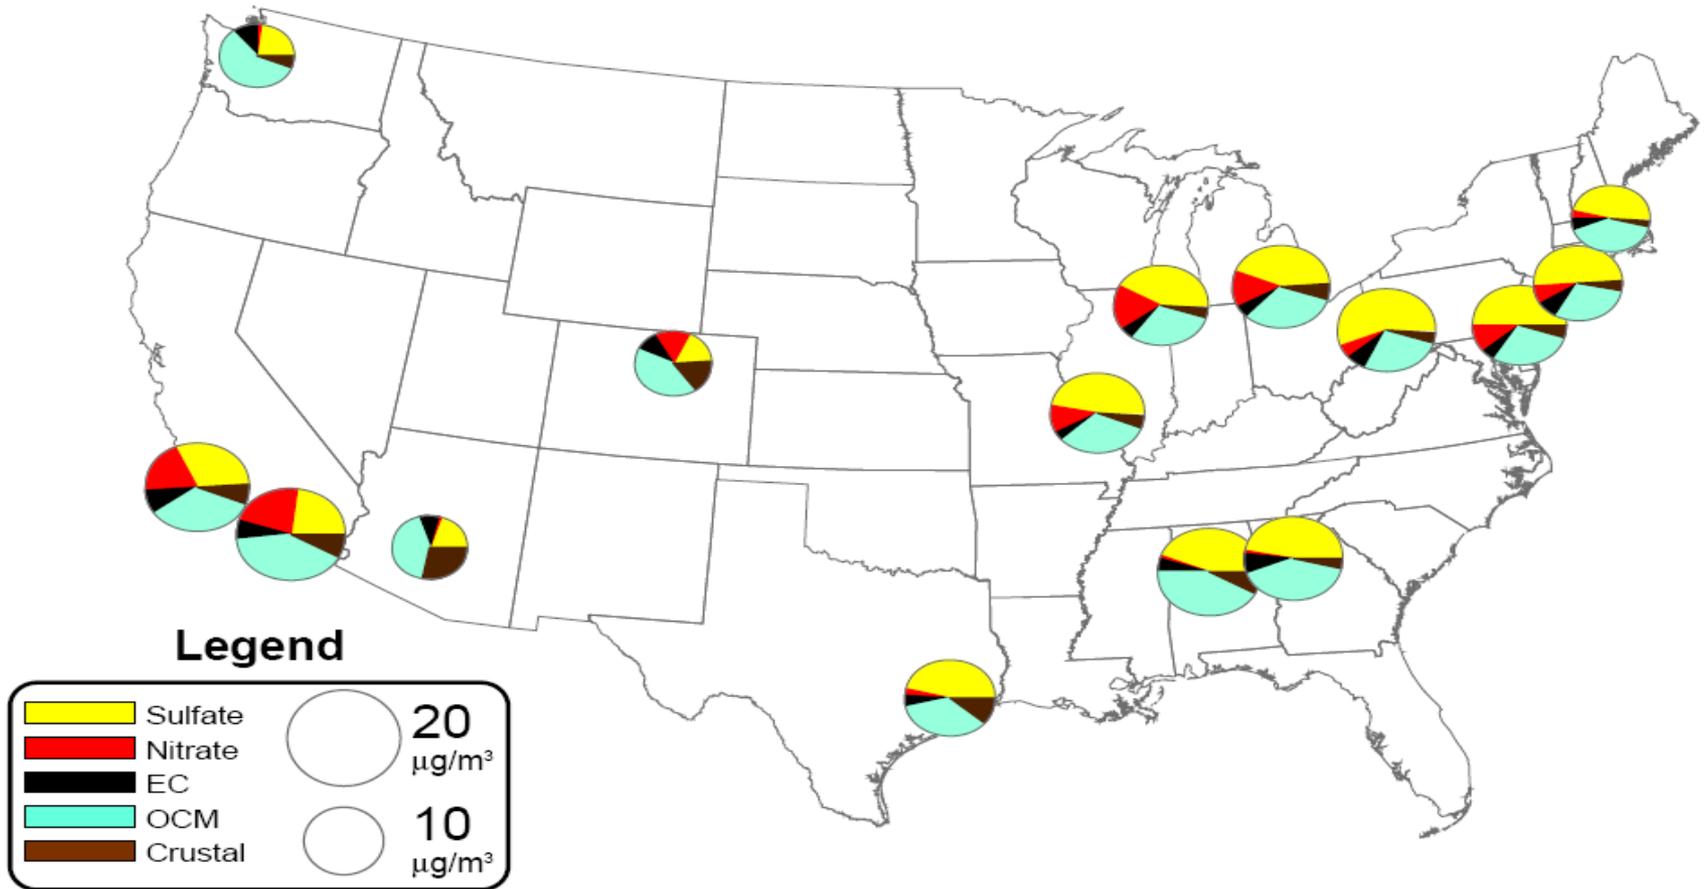

Remand: *Primary Annual PM_{2.5} Standard*

- Court concluded EPA failed adequately to explain why annual PM_{2.5} standard is sufficient to protect public health with an adequate margin of safety
- Remanded annual standard for further consideration of:
 - Whether it provides an adequate margin of safety from the risk of *short-term* exposure to PM_{2.5}
 - Whether it provides an adequate margin of safety against *morbidity in children and other vulnerable subpopulations*

PM_{2.5} National Air Quality – 2007

PM_{2.5} Speciation Select Urban Areas 2005-2007

Evidence-based Considerations

- Evidence-based considerations play central role in reviewing the PM NAAQS
 - Primary emphasis given to epidemiological evidence
 - Controlled human exposure and toxicological studies provide coherence and biological plausibility; support a number of potential biologic mechanisms or pathways for PM-related effects
 - Associations and related uncertainties generally characterized with regard to different size fractions, components, sources, and environments
 - Look for trend in ambient levels where adverse health effects are seen across epidemiology studies
 - Decision is complicated by lack of clear threshold, or lowest observable effects level

Effects Associated with Short-term Exposures to PM_{2.5}

- New multi-city U.S. studies
 - Use uniform methodologies to investigate the effects of PM_{2.5} on health with data from multiple locations representing varying regions and seasons representative of different climate and air pollution mixes
- Premature mortality
 - All-cause
 - Cause-specific (cardiovascular- and respiratory-related)
- Morbidity effects as indexed by emergency department (ED) visits and hospitalizations including new Medicare cohort studies
 - Respiratory disease-related
 - Cardiovascular disease-related
- Focusing on effects observed in areas that would meet the current PM_{2.5} NAAQS

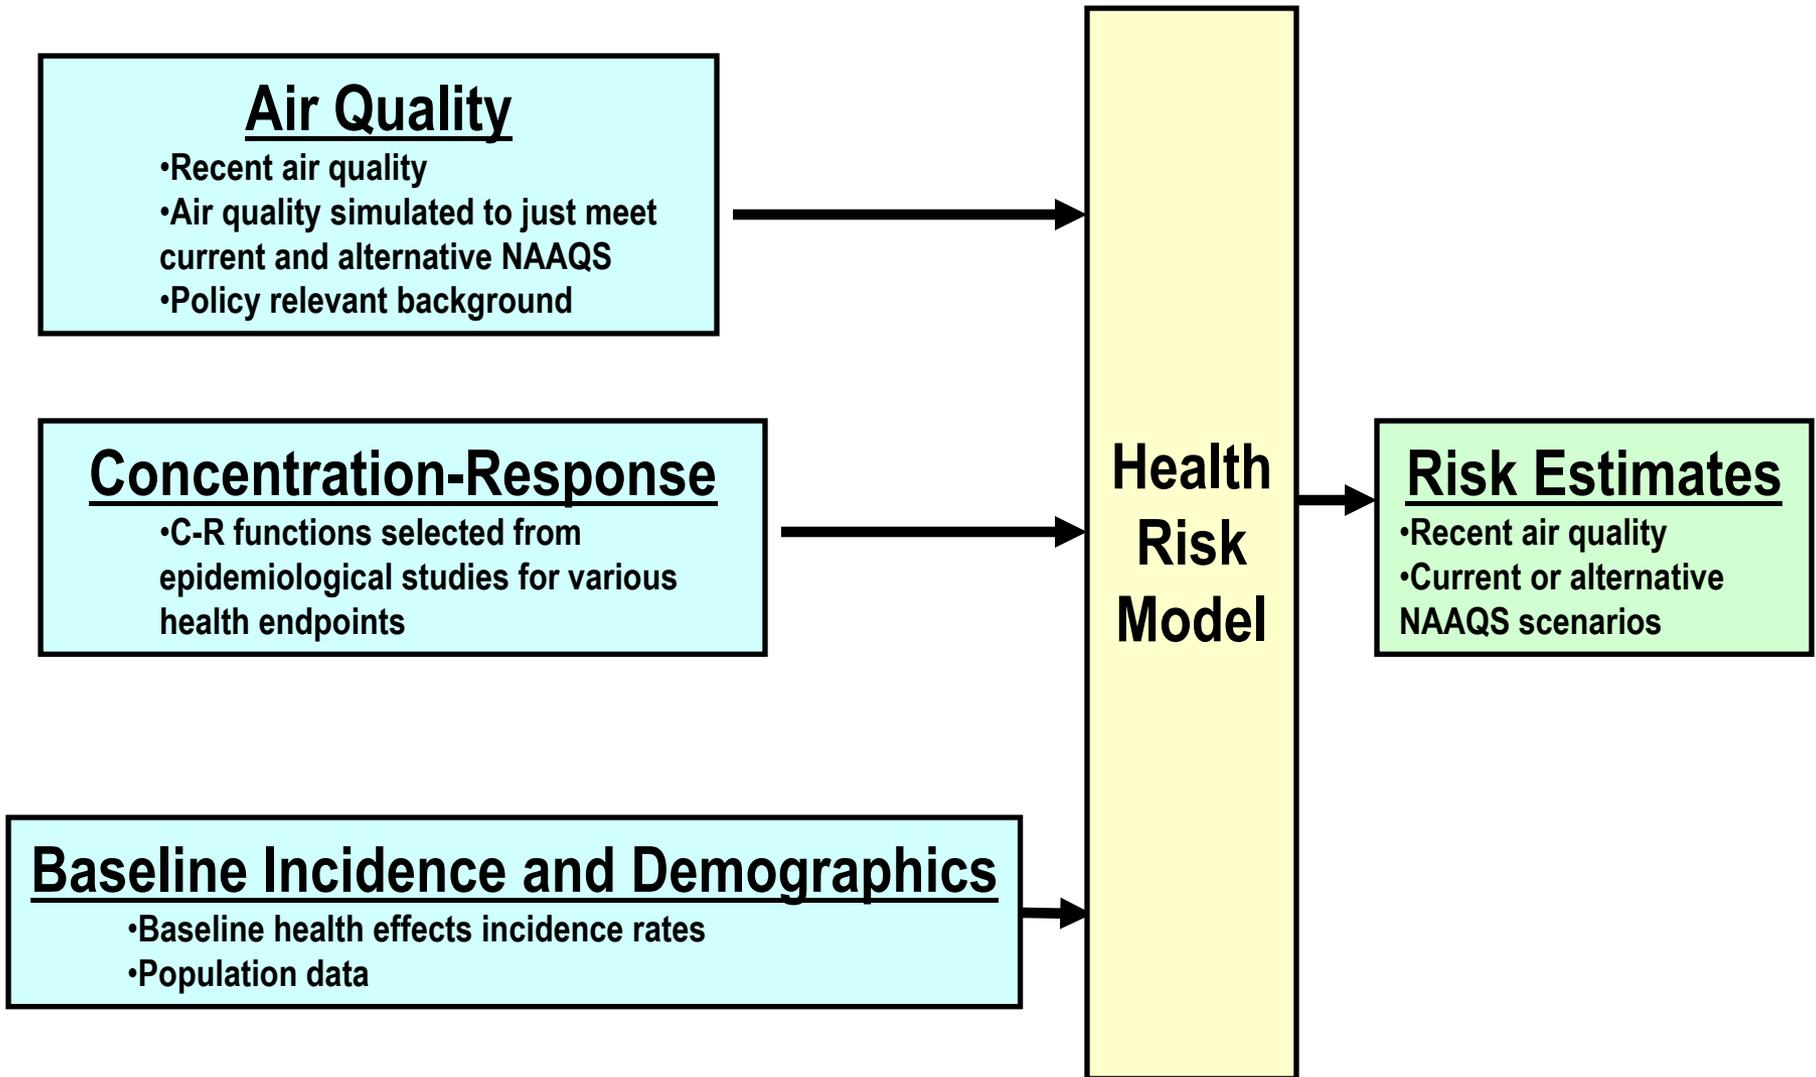

Effects Associated with Long-Term Exposures to PM_{2.5}

- Extended analyses of large multi-city studies largely consistent with previous reports of premature mortality; strongest evidence for cardiovascular-related effects
- New study showing decrease in PM_{2.5} concentrations associated with increased life expectancy
- New evidence of premature mortality and cardiovascular effects in post-menopausal women with no pre-existing cardiovascular effects
- New evidence of effects in at-risk populations
 - Extended analyses of So. California Children's Health Study provide further evidence of respiratory symptoms and reduced lung function growth
 - New study of cystic fibrosis cohort
 - Emerging evidence for developmental effects
- Focusing on effects observed in areas that would meet the current PM_{2.5} NAAQS

Effects Associated with Short-Term Exposure to PM_{10-2.5}

- More limited air quality data to consider in evaluating health evidence; measurement errors larger than for PM_{2.5}
- New multi-city US studies provide evidence of premature mortality
 - Different methods used for estimating ambient concentrations
 - Co-pollutant confounding
- Morbidity
 - Most consistent evidence is for asthma-related outcomes among children
 - Less consistent evidence among adults

Overview of PM Risk Assessment Model

Quantitative Risk Assessment

15 urban study areas and 7 regions

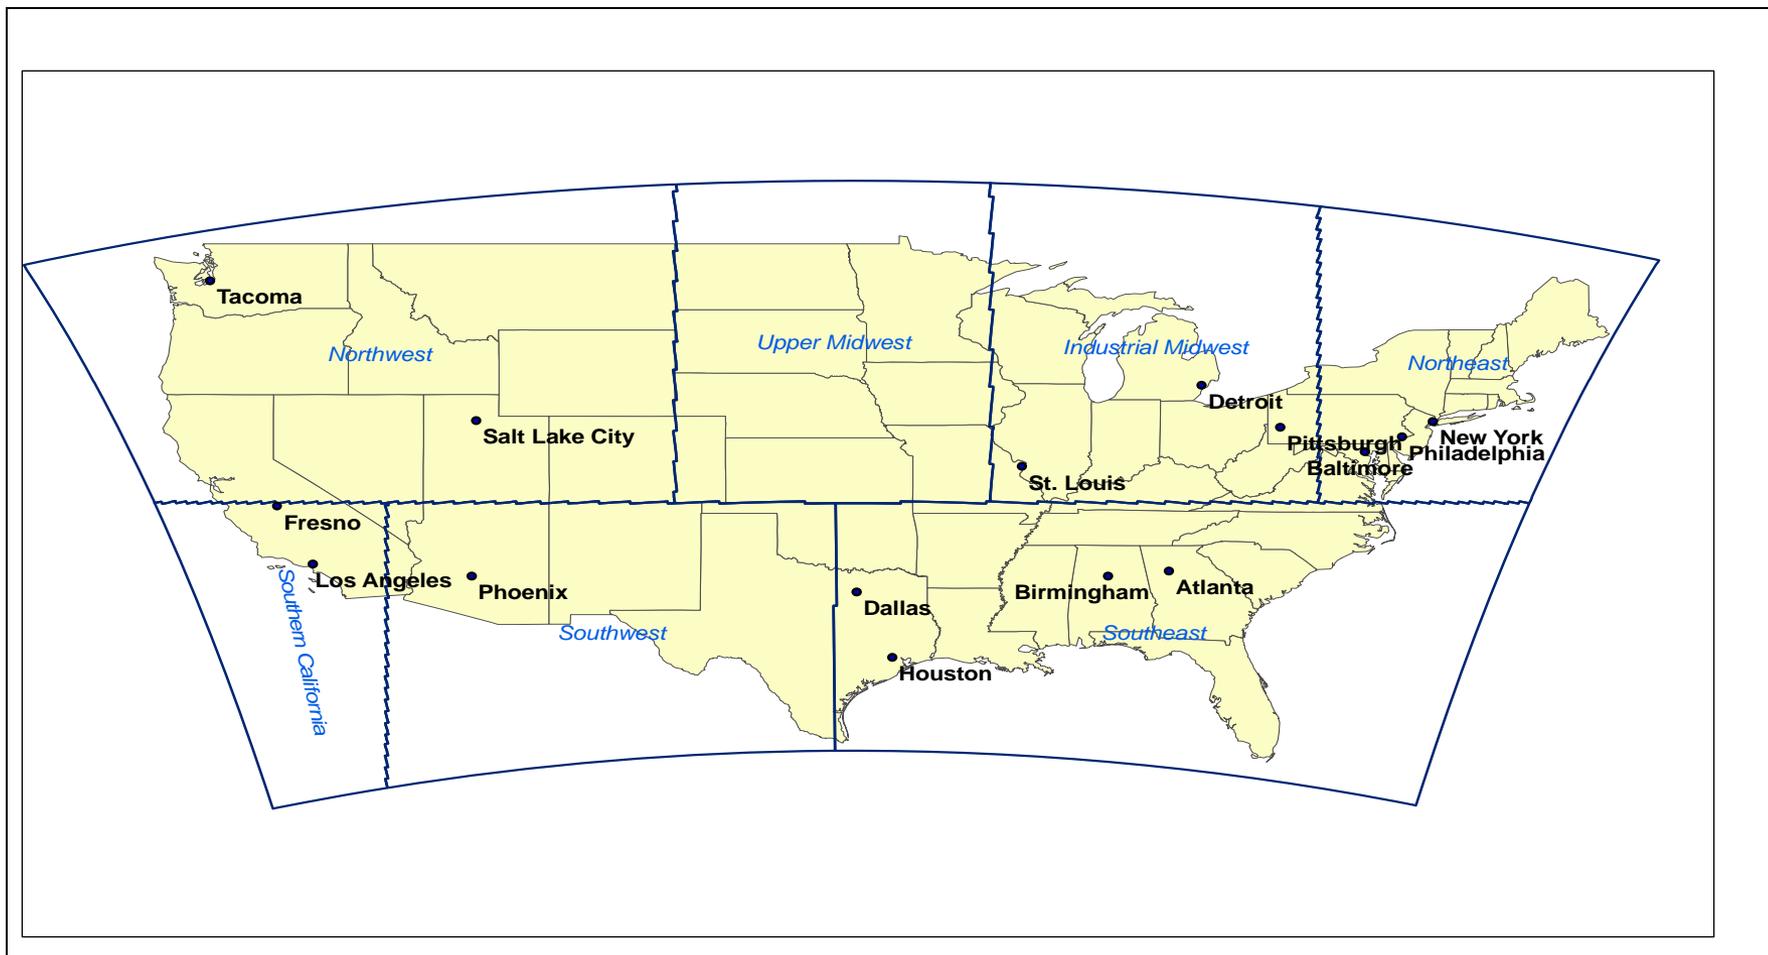

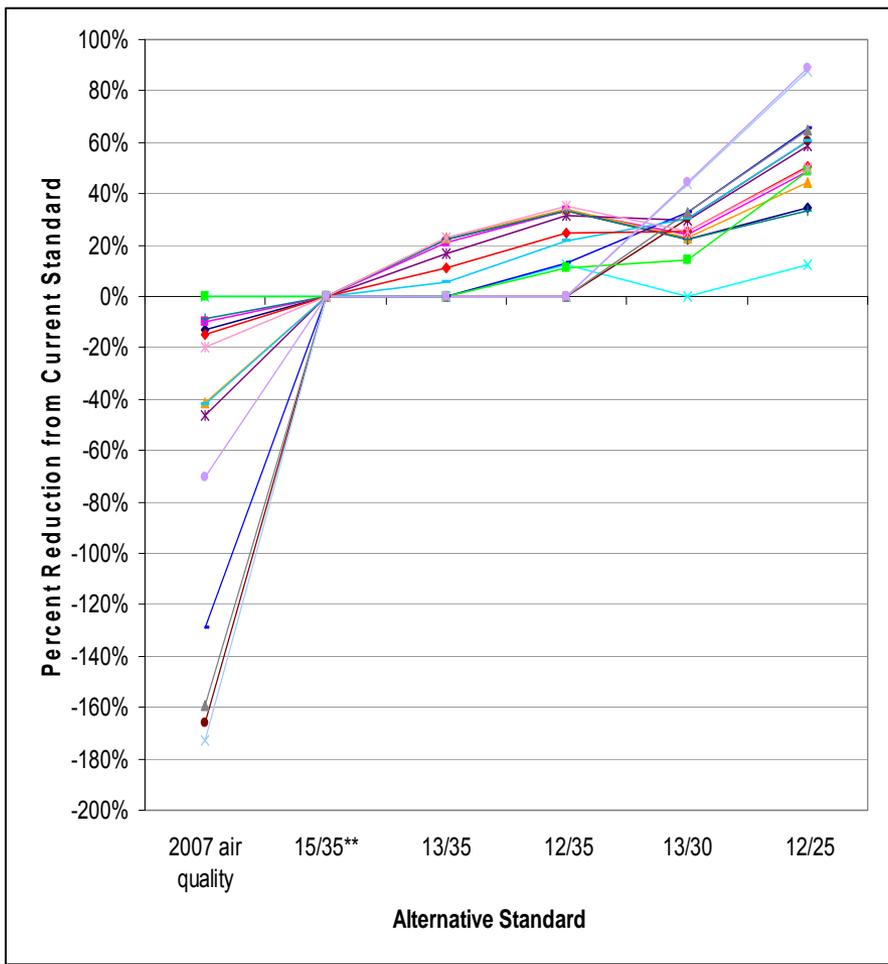

Figure 4-1. Estimated Percent Reductions From the Current Standards to Alternative Set of Standards in All Cause Mortality Associated with Long-Term Exposure to PM2.5 (source: US EPA, 2009)

incidence estimate (and 95% CI) and the estimate of percent of total incidence (and 95% CI) under the current

- ◆ Atlanta, GA 571 (370 - 769); 3.6% (2.3% - 4.8%)
- ◆ Baltimore, MD 439 (284 - 592); 3.1% (2% - 4.2%)
- ◆ Birmingham, AL 335 (217 - 451); 3.3% (2.2% - 4.5%)
- ◆ Dallas, TX 311 (201 - 420); 2.3% (1.5% - 3.1%)
- ◆ Detroit, MI 366 (236 - 494); 2.1% (1.3% - 2.8%)
- ◆ Fresno, CA 112 (73 - 152); 2% (1.3% - 2.6%)
- ◆ Houston, TX 687 (445 - 926); 3.5% (2.3% - 4.7%)
- ◆ Los Angeles, CA 979 (632 - 1323); 1.7% (1.1% - 2.3%)
- ◆ New York, NY 1067 (690 - 1442); 2% (1.3% - 2.7%)
- ◆ Philadelphia, PA 413 (267 - 557); 2.8% (1.8% - 3.8%)
- ◆ Phoenix, AZ 451 (292 - 610); 1.8% (1.2% - 2.5%)
- ◆ Pittsburgh, PA 236 (153 - 319); 1.7% (1.1% - 2.3%)
- ◆ Salt Lake City, UT 52 (34 - 71); 1% (0.7% - 1.4%)
- ◆ St. Louis, MO 545 (353 - 735); 2.9% (1.9% - 3.9%)
- ◆ Tacoma, WA 53 (34 - 72); 1% (0.7% - 1.4%)

Next Steps in Current PM NAAQS Review

- Finalize assessment documents – Dec 2009
 - Integrated Science Assessment
 - Quantitative Risk Assessment
 - Urban-focused Visibility Assessment
- Develop external review draft Policy Assessment for CASAC review and public comment – Feb 2010

Nitrogen Dioxide (NO₂)

Background: History of the NO₂ NAAQS

- 1971: Primary NAAQS set at 0.053 parts per million (ppm) (equivalent to 53 ppb), annual average
 - Based on epidemiologic studies that reported associations of long-term exposure to NO₂ with respiratory illness and lung function in children
 - Quantitative basis for the annual standard level was later called into question
- 1985 and 1996: Existing standard retained
 - Standard would maintain annual NO₂ concentrations considerably below long-term levels for which serious chronic effects have been observed in animals
 - Areas that met an annual standard of 53 ppb unlikely to experience 1-hour NO₂ concentrations that had been associated with respiratory effects in controlled human exposure studies
- September 2005: Deadline suit filed by Center for Biological Diversity (and others)
- Current Review scheduled to be completed on or before Jan 22, 2009

Background: NO₂ Air Quality

- All areas of the U.S. are currently in attainment
- Annual average ambient NO₂ levels, as measured at fixed-site monitors, decreased 41% between 1980 and 2006
 - National average now about 10-20 ppb
- However, because mobile sources are important sources of NO₂, concentrations on/near roadways can be appreciably higher than concentrations measured at fixed-site ambient monitors
 - Can be 30 to 100% higher near roads and 2- to 3-fold higher in vehicles
- Therefore, short-term NO₂ exposures would be considerably higher than indicated at ambient monitors in individuals who spend time near roadways and/or in vehicles on major roadways

Evidence for NO₂-Related Health Effects

- For purposes of characterizing health risks, focused on endpoints for which the evidence was judged sufficient to infer a *causal* or *likely causal* relationship
 - Adverse respiratory morbidity (e.g., respiratory symptoms, ED visits, hospital admissions, physiological endpoints)
 - Support comes from epidemiologic, controlled human exposure, and animal toxicological studies
- Evidence-based considerations including additional endpoints with *suggestive* evidence of a causal relationship
 - Cardiopulmonary and non-accidental mortality with short-term exposure
 - Respiratory morbidity with long-term exposure

NO₂: Overview of Epidemiologic Evidence

- Epidemiologic studies provide the strongest evidence supporting a link between NO₂ and adverse respiratory effects
 - A large number (50+) of studies of respiratory morbidity effects (i.e., symptoms, ED visits, hospital admissions) and short-term NO₂ exposure published since previous NO₂ NAAQS review
 - Look for trend in ambient levels where adverse health effects are seen across studies
 - Ambient, indoor, and personal NO₂ concentrations evaluated
 - Consistent results reported in studies of ambient concentrations conducted in multiple U.S. cities (e.g., Atlanta, LA, NYC) as well as cities in Canada, Asia, and Europe
 - In the locations where a number of these studies were conducted, NO₂ concentrations were below levels allowed by the current NO₂ NAAQS

Health Effects of NO₂: Overview of Controlled Human Exposure Evidence

- EPA conducted a meta-analysis that combined individual data from 19 separate studies on airway responsiveness in asthmatics
- Meta-analysis reported that most asthmatics experienced an increase in airway responsiveness following exposure to NO₂ concentrations at or above 100 ppb
 - Approximately 70% of asthmatics experienced an increase

Rulemaking

- Proposed rule – July 15, 2009 - (74 FR 34404)
 - Scientific evidence
 - Calls into question the adequacy of the current standard to protect public health
 - Supports consideration of a short-term standard to provide increased health protection for at-risk populations
 - Exposure- and risk-based assessments reinforce need to revise current standard so as to provide increased public health protection
 - Proposed to strengthen the primary NAAQS by:
 - Adding a 1-hour NO₂ standard at a level between 80-100 ppb to focus on peak short-term exposures
 - Retaining annual NO₂ standard at a level of 53 ppb
 - EPA also proposed changes to the NO₂ air quality monitoring network
- Final rule – January 22, 2010

Revision to NAAQS for Lead October 2008

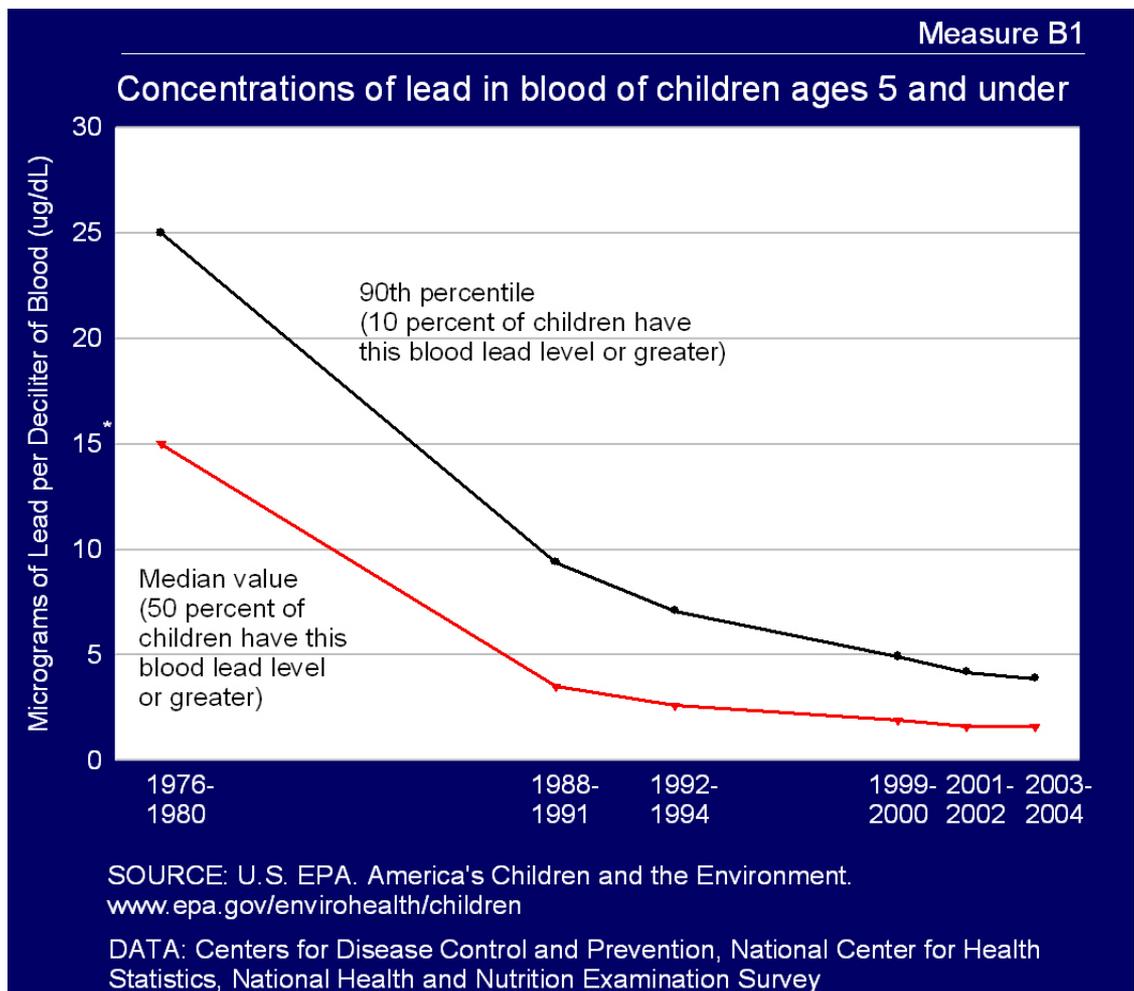

Background - Lead (Pb) Air Pollution

- Pb occurs naturally and is emitted by many anthropogenic sources
 - Highest levels are generally found near lead smelters
- Pb is generally emitted into the air in the form of particles
 - Can end up in water, soil and dust on surfaces
- People are exposed by inhaling Pb in air or ingesting Pb that has settled onto surfaces or soils
 - Ingestion is the main route of human exposure to air Pb
 - Children are more likely to be exposed to Pb because they exhibit greater “hand-to-mouth” activity
 - Once in the body, Pb is rapidly absorbed into the bloodstream
- Pb is persistent
 - People can be exposed to Pb emitted just yesterday or years ago

Impacts of Lead on Public Health

- Broad range of health effects
 - Damage to the central nervous system, cardiovascular system, kidneys, immune system and red blood cells
- Effects in children include:
 - Effects on developing nervous system, which can cause impacts into adulthood include
 - IQ loss
 - Poor academic achievement, permanent learning disabilities, increased risk of delinquent behavior
 - Weakened immune system
- Effects in adults include:
 - Increased blood pressure
 - Cardiovascular disease
 - Decreased kidney function

Changes in Children's Blood Lead Levels Since 1978

- Significant reduction
 - From a median of 15 $\mu\text{g}/\text{dL}$ in late 1970s to 1.6 $\mu\text{g}/\text{dL}$ in 2003-04

New Health Evidence in Recent Review

- Many new studies published since standard set in 1978
 - >6,000 published since 1990
- Serious health effects shown to occur at much lower blood Pb levels than those recognized as harmful in late 70s
 - Strong evidence of adverse effects at blood Pb levels well below 10 micrograms per deciliter ($\mu\text{g}/\text{dL}$)
 - No threshold or “safe” level for lead in blood has been identified
- Epidemiological studies in children demonstrate associations of blood Pb levels with loss of IQ and other neurocognitive effects
 - Results are remarkably consistent across numerous studies with varying designs and study populations
 - Associations have continued to be observed in most recent studies involving populations with lower blood Pb levels
 - The evidence indicates that the effect of Pb on IQ on incremental basis (per $\mu\text{g}/\text{dL}$) is greater at lower blood lead levels

Revisions to the Lead Standards: Level

- 1978 standard of $1.5 \mu\text{g}/\text{m}^3$ not requisite to protect public health with an adequate margin of safety
 - Health effects demonstrated at much lower exposures that we understood in the past
- Primary standard strengthened to a level of $0.15 \mu\text{g}/\text{m}^3$
 - Provides increased protection for public health
 - Especially the health of children and particularly for children near sources, where air levels are highest
 - In combination with decisions on indicator, averaging time and form - provides requisite protection of public health, including health of sensitive groups, with an adequate margin of safety

Revisions to the Lead Standards: Level (continued)

- **Primary standard strengthened to a level of $0.15 \mu\text{g}/\text{m}^3$**
 - Decision guided by framework that integrates evidence for relationships between ...
 - Pb in air and Pb in children's blood
 - Studies of children whose Pb exposures differ mainly with regard to air Pb levels
 - Pb in children's blood and IQ loss
 - Studies of children's IQ and blood Pb, with control for major IQ-influencing factors
 - Level of $0.15 \mu\text{g}/\text{m}^3$ estimated to protect against air Pb-related IQ loss in most exposed children
 - Based on weight of scientific evidence
 - Quantitative risk assessment results supportive of framework estimates

Revisions to the Lead Standards: Averaging Time and Form

- New standard is in terms of a maximum (not-to-be-exceeded) rolling three-month average evaluated over a three-year period.
- As compared to previous averaging time of calendar quarter, new standard is:
 - More scientifically appropriate
 - Rolling average gives equal weight to all three-month periods, and
 - New calculation method gives equal weight to each month within each three-month period
 - More health protective
 - Rolling average yields 12 three-month averages each year to be compared to the NAAQS (*versus* four averages in each year for block calendar quarters)

Revisions to the Lead Standards: Indicator

- Pb in total suspended particles (Pb-TSP) retained as indicator
 - Reflects evidence that Pb particles of all sizes pose health risks
- Use of Pb-PM₁₀ monitoring allowed in place of Pb-TSP monitoring in certain limited circumstances
