ABSTRACT

This is a final report on a test program to evaluate the long term effectiveness of combustion modifications on industrial boilers. During previous programs short term tests have been performed on industrial boilers to determine the effect of combustion modifications on air pollutant emissions such as NO_x, SO_x, CO, HC, and particulate. The objective of this program was to determine whether the combustion modification techniques which were effective for short duration tests are feasible for a longer period. This report presents results of a 30-day field test of a 26.4 MW output (90,000 lb steam/hr) residual-oil-fired boiler. The NO_x control technology employed on this unit was staged combustion air. The as found concentration of NO_x was 130 ng/J (235 ppm at 3% O_2, dry). Firing in the low NO_x mode, with staged combustion air, resulted in a reduction in NO_x emission of approximately 23 percent to 100 ng/J (181 ppm at 3% O_2, dry).

SECTION 1.0

SUMMARY

1.1 OBJECTIVE AND SCOPE

The objective of this field test was to determine whether combustion modification techniques which demonstrated reductions in air pollutant emissions during short-term tests are feasible for longer periods. In addition, boiler performance and reliability were monitored. The combustion modifications have previously been shown to be effective on industrial boilers. (Reference 1 and 2).

The program scope provided for thirty-day field tests of a total of seven industrial boilers with design capacities ranging from 14.65 to 73.25 MW output (50,000 to 250,000 lb steam/hr). This final report is for the second of the seven, a 26.4 MW output (90,000 lb steam/hr) residual-oil-fired boiler using staged combustion air and low excess air as the NO_x emission control technology.

During the test period, continuous-monitor certification tests were performed concurrently with low NO_x testing. Emissions measured were particulate, NO, CO_2, CO, and O_2. Boiler efficiency was measured several times during the program to determine the effect of combustion modification on boiler efficiency.

This is a final report on the thirty-day test documenting the test equipment, a summary of the test data, and a discussion of the data in relation to the control technology employed for this type of boiler.

1.2 RESULTS

The initial task of this program was to select industrial boiler test sites which fit the categories set forth in the statement of work. Further, it was desired to find a site which had previously been tested to minimize the setup time and eliminate the need for extensive combustion modification testing. A survey of previous test sites was made to locate a residual-oil-fired boiler which employed staged combustion air and low excess air as the NO_x control technologies. Boilers which were tested by KVB under previous programs (cited in the document footnoted on the previous page) were reviewed. The boiler which best met the above criteria was selected for testing.

Following test site selection, the KVB continuous monitor was shipped to the site and installed. Continuous-monitor certification tests, as outlined in Performance Specifications 2 and 3, 40 CFR 60, Appendix B, were then begun.

The 30-day field test was begun after the continuous monitor certification tests were completed. The test was performed according to "Plan for Performing Source Evaluation Tests in Support of the NSPS for Industrial Boilers." Emissions of NO, CO, CO_2 and O_2 were measured continuously. Particulate measurements were made in triplicate at the start, midpoint and conclusion of the test period. Triplicate particulate measurements were also made with the boiler in the as-found condition. Measurements of polycyclic organic matter were made in both the modified and as-found conditions.

The results of the 30-day test are discussed in detail in Section 3.0.

Table 1-1 is a summary of the 24-hour averages of gaseous emissions compiled from the analyzer strip chart recordings and plant steam flow charts. An analysis of the field test data was prepared. A log-probability plot of 24-hour averages is presented in Figure 1-1 for the low NO_x condition. The mean value for the NO is 100 ng/J with a geometric dispersion of 1.12.

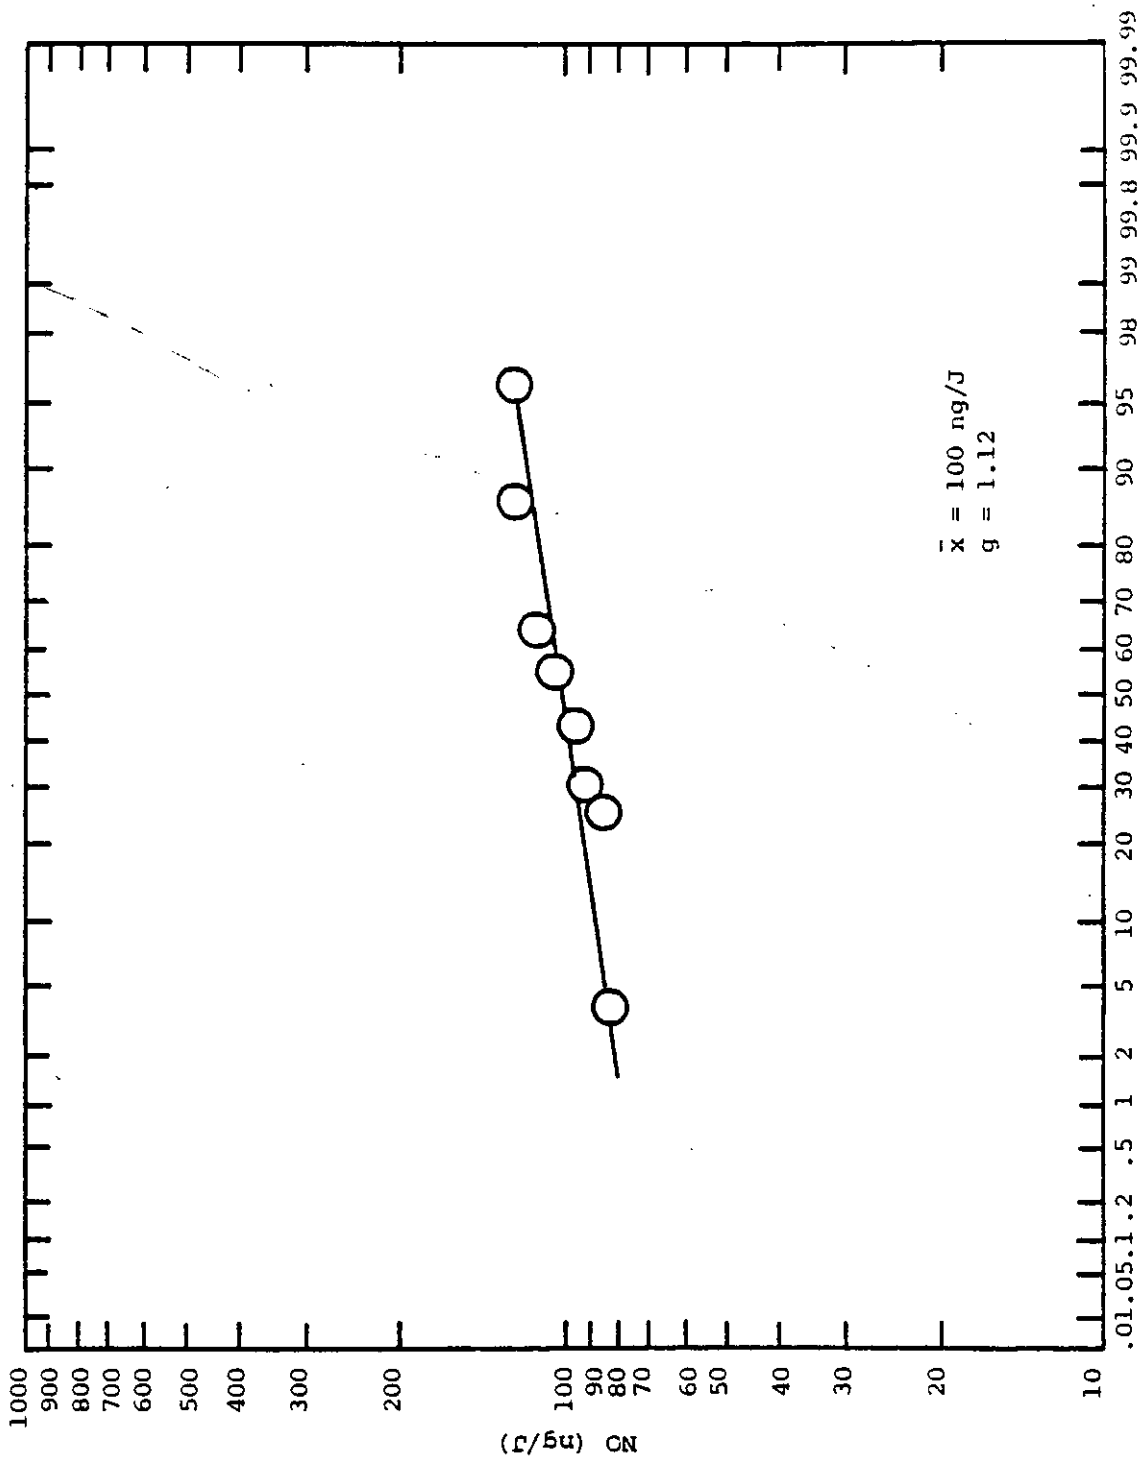

Figure 1-1. Site 2 - Residual Oil Fired Boiler-Staged Combustion Air (BOOS)

1.3 CONCLUSIONS

Based on the results of this 30-day field test, several important conclusions can be drawn.

1. Staged combustion air (SCA) is an effective NO_x control technology for residual-oil-fired boilers. Staged combustion air was achieved by removing one burner from service in a triangular burner pattern. Removing one burner from service resulted in an NO emission level of 100 ng/J (178 ppm at 3 percent O_2, dry). This level represents a reduction of approximately 23 percent from the condition where all burners are firing. All burners firing produce NO emissions of 130 ng/J (232 ppm at 3 percent O_2 dry). It was not possible to operate the entire test with one burner out of service due to steam demand. As a result, the average NO emission level for the 30-day test was 110 ng/J (196 ppm at 3 percent O_2, dry).

2. Operation of the boiler in the low NO_x mode resulted in 48 percent higher particulate emissions than did normal operation. The particulate emission level with all burners firing was 25.6 ng/J (0.0594 lb/10^6 Btu), while the low NO_x mode with one burner out of service resulted in 37.8 ng/J (0.0878 lb/10^6 Btu).

3. Boiler operation with one burner out of service results in reduced capacity for the boiler due to oil supply pressure limitations. In order to operate at full capacity with two burners, new oil tips would be required. These were not available for this test.

4. The continuous-monitor system utilizing an extractive sample system provided accurate, reliable data. The NO analyzer was out of service for two days during the duration of the test. The CO analyzer was out of service 23 days during the same period.

5. POM measurements showed a slight decrease when operating in the low NO_x mode. Total POM in the baseline condition were 7.6 <11.36 $\mu g/m^3$ and 4.6 <9.7 $\mu g/m^3$ in the low NO_x mode.

SECTION 2.0

INSTRUMENTATION AND PROCEDURES

This section presents a description of the instrumentation used to measure the gaseous and particulate emissions, the test procedures, the techniques for certifying the continuous monitor, and a description of the boiler tested.

2.1 EMISSIONS MEASUREMENT INSTRUMENTATION

The emissions measurements were made using a continuous monitor fabricated by KVB for this program. The analytical instrumentation and sample handling equipment are contained in a cabinet 1.2 m wide x 0.76 m deep x 183 m high (48"W x 30"D x 72"H). A photograph of the continuous monitor is shown in Figure 2-1. Gaseous emission measurements were made with the analytical instruments listed in Table 2-1.

Total particulate measurements were made using an EPA Method 5 sampling train manufactured by Western Precipitation Division of Joy Manufacturing Company. Samples for measurement of polycyclic organic matter (POM) were obtained using an XAD-2 module supplied by Battelle Columbus Laboratories. These modules were returned to Battelle for analysis following the test.

2.1.1 Gaseous Emissions

The continuous monitor is equipped with analytical instruments to measure concentrations of NO, CO, CO_2, and O_2. The sample gas is delivered to the analyzers at the proper condition and flow rate through the sampling

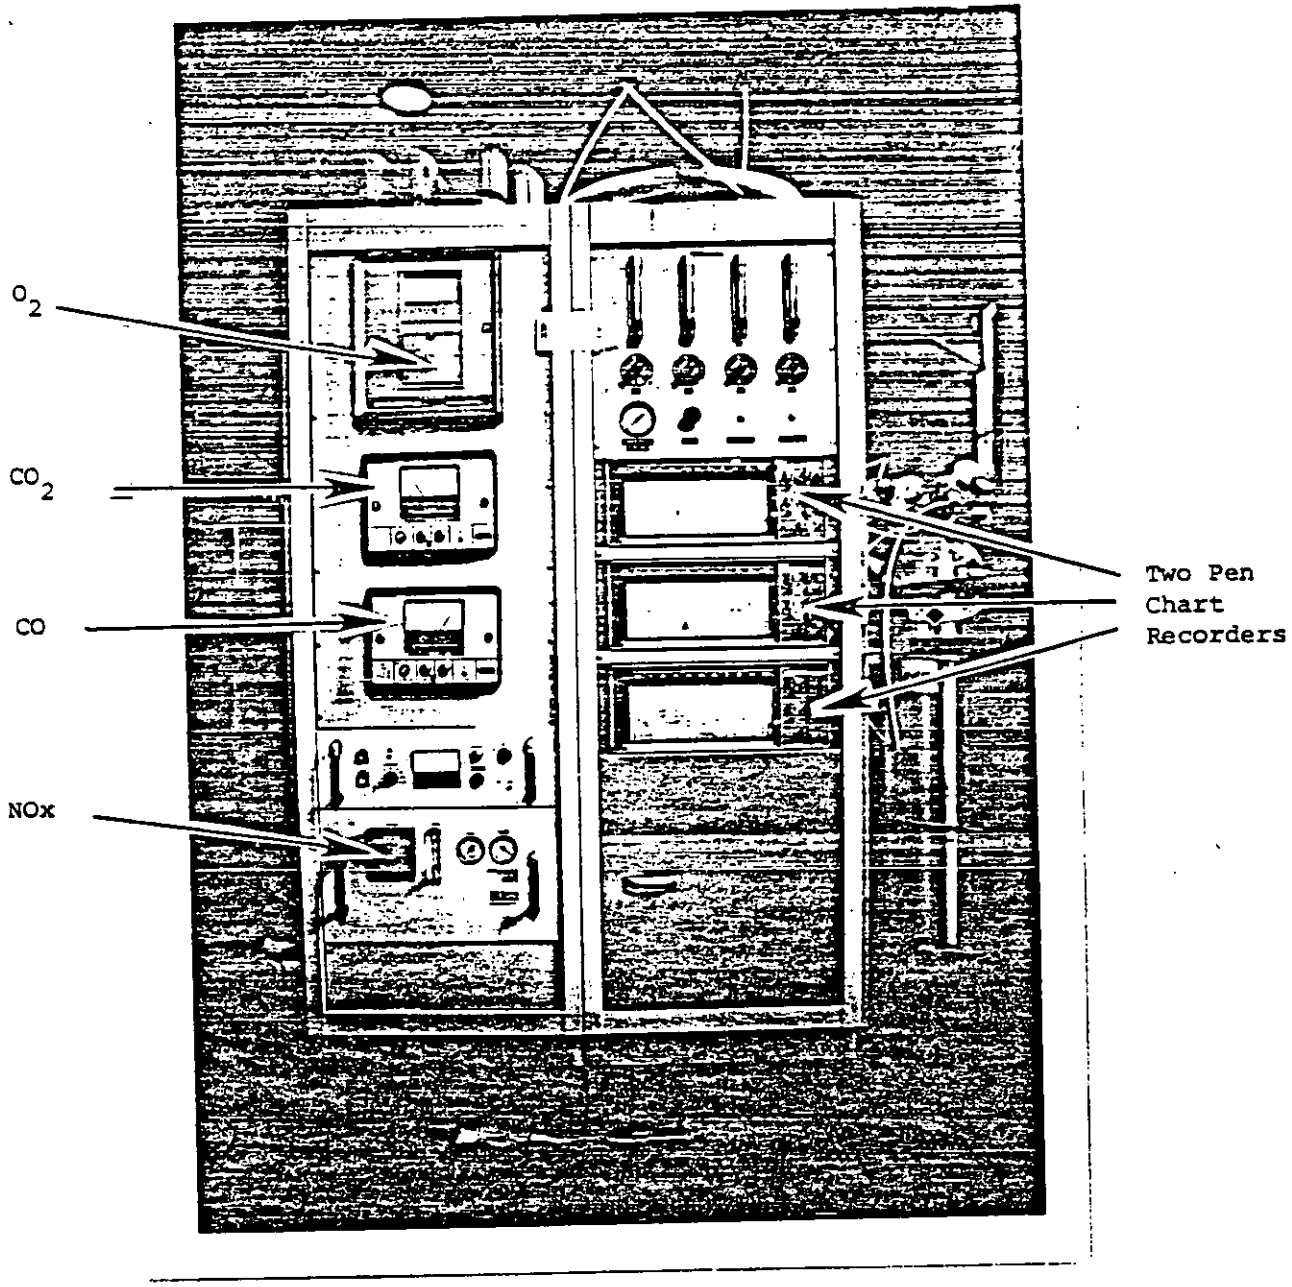

Figure 2-1. Photograph of KVB Continuous Monitor for Measuring Gaseous Emissions

TABLE 2-1. ANALYTICAL INSTRUMENTATION

Emission Species	Manufacturer	Measurement Method	Model No.
Nitrogen Oxides	Thermo Electron	Chemiluminescent	10A
Oxygen	Beckman Instrument	Polarographic	742
Carbon Dioxide	Horiba Instrument	NDIR	PIR-2000

Opacity	Dynatron	Transmissometer	1100

and conditioning system shown schematically in Figure 2-2. A probe with a 0.7-micrometer sintered stainless steel filter was installed in the stack to sample the flue gas. The following paragraphs describe the analytical instrumentation.

A. Nitrogen Oxides--

The oxides of nitrogen monitoring instrument used was a Thermo Electron chemiluminescent nitric oxide analyzer. The operational basis of the instrument is the chemiluminescent reaction of NO and O_3 to form NO_2 in an excited state. Light emission results when excited NO_2 molecules revert to their ground state. The resulting chemiluminescence is monitored through an optical filter by a high sensitivity photomultiplier tube, the output of which is electronically processed so it is linearly proportional to the NO concentration.

Air for the ozonator is drawn from ambient through an air dryer and a 10-micrometer filter element. Flow control for the instrument is accomplished by means of a small bellows pump mounted on the vent of the instrument downstream of a separator which insures that no water collects in the pump.

The basic analyzer is sensitive only to NO molecules. To measure NO_x (i.e., NO + NO_2), the NO_2 is first converted to NO. This is accomplished by a converter which is included with the analyzer. The conversion occurs as the gas passes through a thermally insulated, resistance heated, stainless steel coil. With the application of heat, NO_2 molecules in the sample gas are reduced to NO molecules, and the analyzer then reads NO_x. NO_2 is obtained by the difference in readings obtained with and without the converter in operation.

Specifications

Accuracy: 1 percent of full scale
Span drift: ± 1 percent of full scale in 24 hours
Zero drift: ± 1 ppm in 24 hours

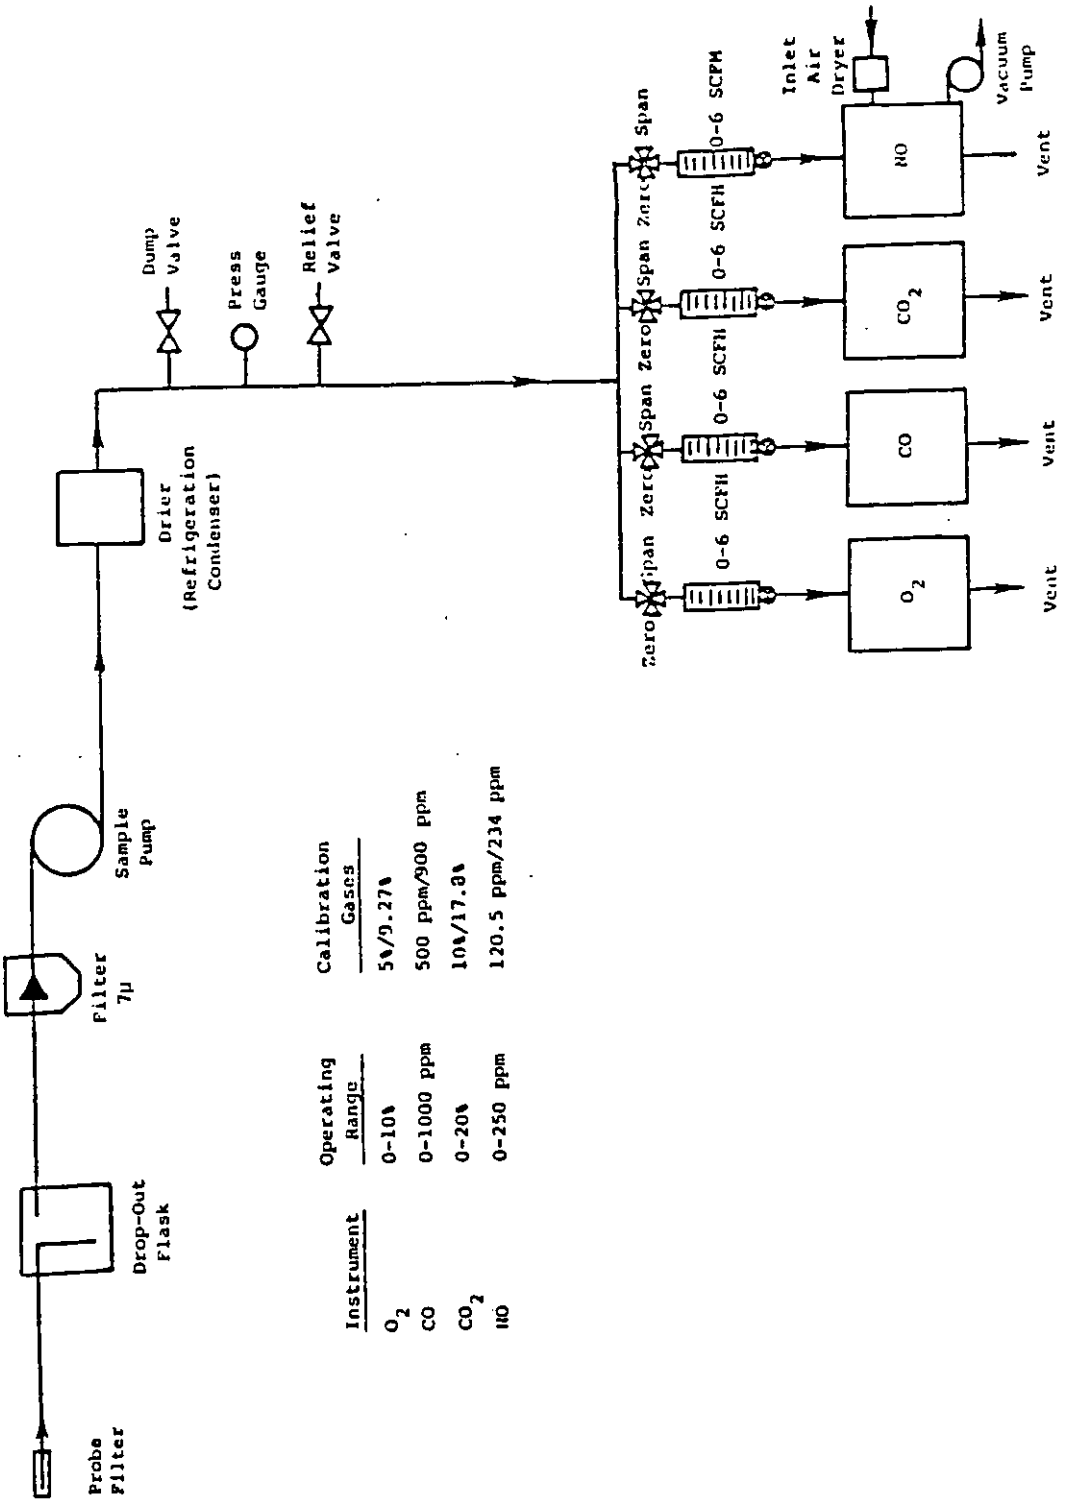

Figure 2-2. Schematic of continuous monitor sampling and conditioning system.

Power requirements: 115 ± 10V, 60 Hz, 1000 watts

Response: 90 percent of F.S. in 1 sec (NO_x mode); 0.7 sec (NO mode)

Output: 4 to 20 ma

Sensitivity: 0.5 ppm

Linearity: ± 1 percent of full scale

Vacuum detector operation

Range: 2.5, 10 25, 100, 250, 1000, 2500, 10,000 ppm F.S.

Only the NO concentration was measured during this program. Because of the added complexity of heated sample lines and controllers necessary for measuring NO_2 and the small percentage of NO_2 in the flue gas, based on previous tests (Reference 1, 2 and 3) EPA decided that only NO measurement was necessary. Therefore, an unheated sample line was installed and the moisture was removed from the sample gas by a dropout flask and a refrigerated condenser.

B. Carbon Monoxide and Carbon Dioxide--

Carbon monoxide (CO) and carbon dioxide (CO_2) concentrations were measured by Horiba Instruments PIR-2000 short-path-length nondispersive infrared analyzers. These instruments measure the differential in infrared energy absorbed from energy beams passed through a reference cell (containing a gas selected to have minimal absorption of infrared energy in the wave length absorbed by the gas component of interest) and a sample cell through which the sample gas flows continuously. The differential absorption appears as a reading on a scale of zero to 100 percent and is then related to the concentration of the species of interest by calibration curves supplied with the instrument. A linearizer was supplied with the CO analyzer to provide a linear output over the range of interest. The operating ranges for the CO analyzer are zero to 500, zero to 1000, and zero to 2000 ppm, and the ranges for the CO_2 analyzer are zero to 5, zero to 10, and zero to 20 percent.

Specifications

Accuracy: 1 percent of full scale

Repeatability: ± 0.5 percent of full scale

Zero drift: ± 1 percent of full scale in 24 hours

Span drift: ± 1 percent of full scale in 24 hours

Response time selectable: 90 percent of full scale in 0.5, 1.2, 3, or 5 seconds

Power requirements: 115 VAC ± 10 percent, 60 Hz

Warmup time: 30 minutes

Output: 0-10 MV

C. Oxygen--

A Beckman Model 742 oxygen analyzer was used to continuously determine the oxygen content of the flue gas sample. The oxygen measuring element contains a silver anode and gold cathode that are protected from the sample by a thin membrane of Teflon. An aqueous KCl solution is retained in the sensor by the membrane and serves as an electrolytic agent. As Teflon is permeable to gases, oxygen will diffuse from the sample to the cathode in the following oxidation-reduction reaction:

Cathode reaction: $O_2 + 2H_2O + 4e \rightarrow 4OH$

Anode reaction: $4Ag + 4Cl \rightarrow 4AgCl + 4e$

With an applied potential between the cathode and anode, oxygen will be reduced at the cathode, causing a current to flow. The magnitude of this current is proportional to the partial pressure of oxygen present in the sample. The instrument has operating ranges of zero to 1 percent, zero to 10 percent, and zero to 25 percent oxygen.

Specifications

Accuracy: ± 1 percent of full scale or ± 0.05 percent O_2, whichever is greater

Sensor stability: ± 1 percent of full scale per 24 hours

Response time: 90 percent in 20 seconds

Output: 0 to 10 MV

Power requirement: 120 ± 10 VAC, 60 Hz

2.1.2 Particulate Emissions

Particulate samples were taken from ports on the vertical side of the rectangular duct at the boiler outlet. The boiler had no port. Four ports were located 0.28 m (11 inches) apart up the side of the duct. The samples were taken using a Joy Manufacturing Company portable effluent sampler. This system, which meets the EPA design specifications for Test Method 5 (Determination of Particulate Emissions from Stationary Sources, Federal Register, Volume 42, No. 160, page 41754, August 18, 1977), is used to perform both the initial velocity traverse and the particulate sample collection. Dry particulates are collected in a heated case that contains, first, a cyclone to separate particles larger than 5 microns and, second, a 100-mm glass-fiber filter for retention of particles as small as 0.3 micrometer. Condensible particulates are collected in a train of four Greenburg-Smith impingers in a chilled water bath.

2.1.3 Polycyclic Organic Matter (POM) Emissions

Particulate and gaseous samples for analysis of POM were taken at the sample port used for Method 5 particulate tests. The sampling system is a modified Method 5 sampling train developed by Battelle Columbus Laboratories. A combination of conventional filtration with collection of organic vapors by means of a high-surface-area polymeric adsorbent (XAD-2) has proved to be highly efficient for collection of all but the more volatile organic species. The modified sampling system consists of the standard EPA train with the adsorbent sampler (Figure 2-3) located between the filter and the impingers. With this system, filterable particulate can be determined from the filter catch and the probe wash according to Method 5; the organic materials present can be determined from the analysis of the filterable particulate and the adsorbent sampler catch. The impingers are only used to cool the stream and protect the dry-gas meter, and their contents are discarded.

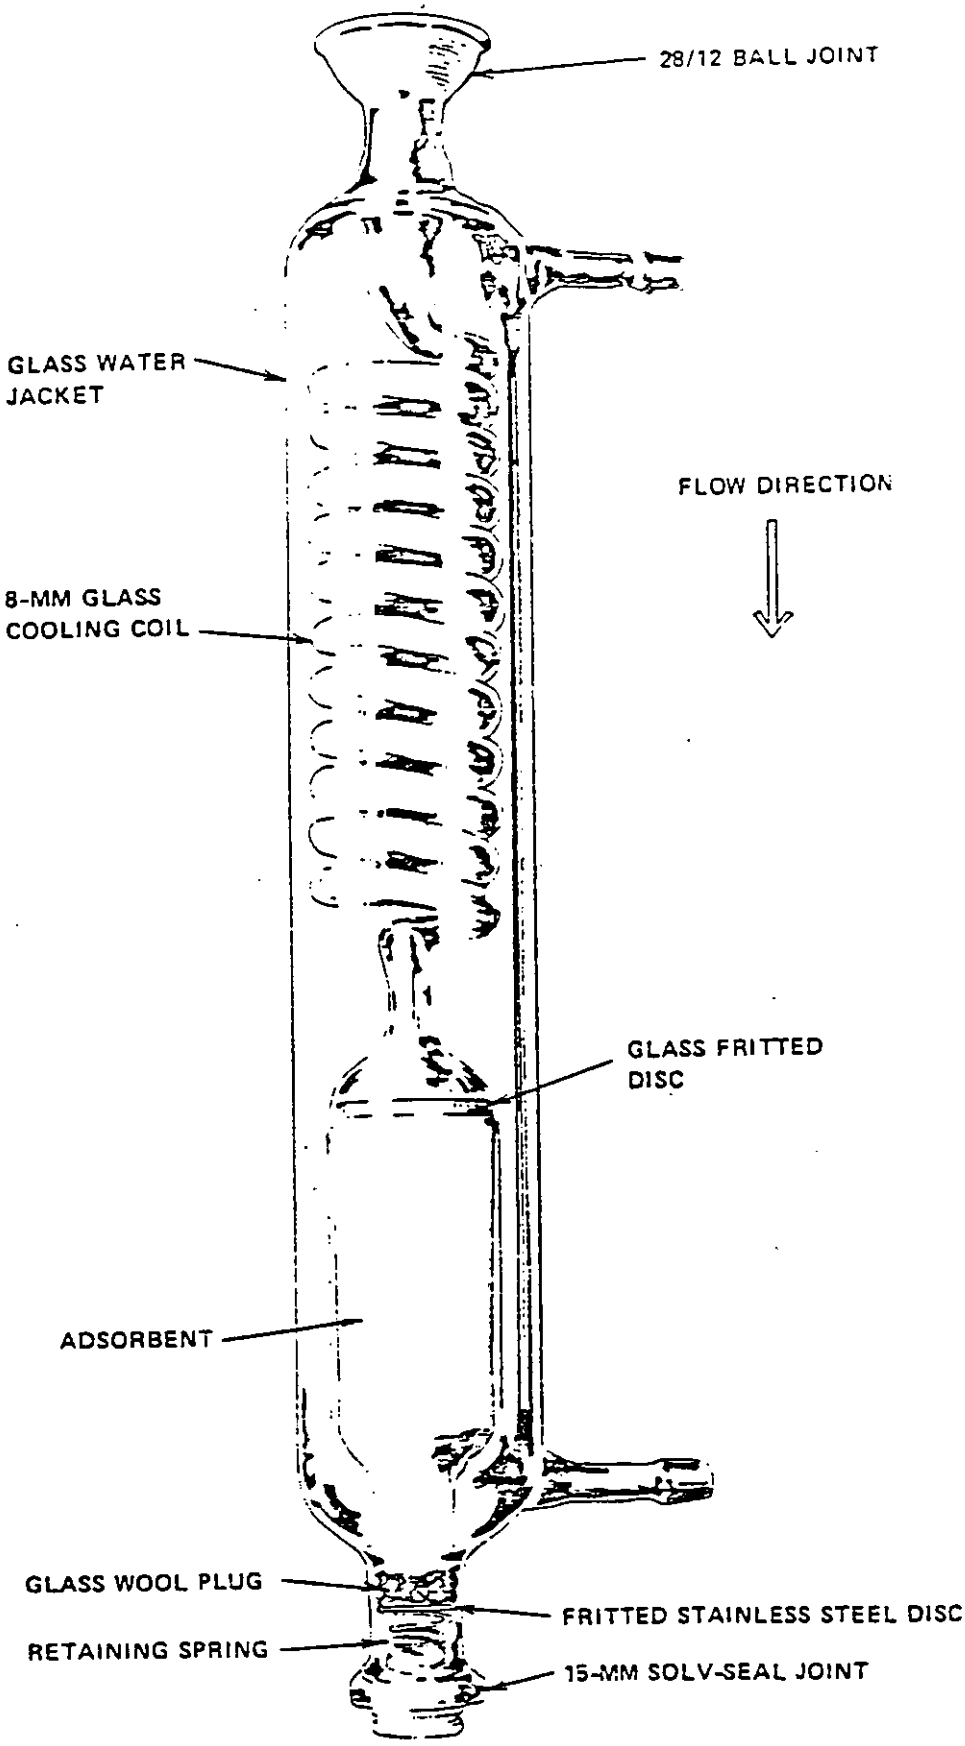

Figure 2-3. Mark III adsorbent sampling system.

2.1.4 Opacity Measurement

Stack opacity was measured with a Dynatron Model 1100 Opacity Monitoring System. The Model 1100 opacity monitor is a double pass transmissometer which measures the light transmittance through a flue gas. The transceiver unit contains the light source, the detector, and electronic circuitry. A reflector is mounted in the end of a slotted probe which is attached to the transceiver and is inserted into a stack or duct through a conventional stack sampling port. The probe causes negligible flow disturbance, and an air purge keeps the optical window and reflector clean. The transceiver output is transmitted to a portable control unit which displays either opacity or optical density automatically correlated from differences between the path length of the transmissometer and the mean diameter of the stack outlet.

Specifications

Peak spectral response: 500 to 600 nm
Mean spectral response: 500 to 600 nm
Relative response: < 10 percent
Angle of view: < 4 degrees
Angle of projection: < 2 degrees
Calibration error: < 2 percent
Response time: 1 second
Zero drift: < 1 percent (24 hours)
Calibration drift: < 1 percent (24 hours)
Operational test period: 168 hours
Output: 0 to 1 VDC
Power requirements: 115 VAC/60Hz
Temperature range: 40°F to 125°F
Weight: 27 pounds (approximate)

The transceiver lenses are cleaned daily, and an air purge is used to keep the lenses free of dirt while inserted in the stack.

2.2 BOILER DESCRIPTION AND CHARACTERISTICS

The boiler at Site 2 was manufactured by Babcock and Wilcox in 1935. It is an integral furnace watertube boiler with an original rated capacity of 26.4 MW (90,000 lb steam/hr). The current top load capability of 79,000 lb steam/hr is limited by the fan. The furnace wall consists of watertubes 76 mm (3 inches) in diameter spaced 260 mm (10.25 inches) on centers. The wall exposure between the tubes consists of refractory; the furnace was rebricked in 1972. The boiler operates at a nominal steam pressure of 2.2 MPa (320 psig) and a steam temperature of 493K (428°F).

The boiler is fired with three B&W steam-atomized burners arranged in a triangular pattern with the top burner spaced directly above the center of the lower two burners. The vertical spacing is 0.91 m (36 inches); the horizontal spacing is 0.94 m (37 inches). The oil guns use a B&W Y-jet steam atomizer with the steam pressure at the burner nominally 0.24 MPa (35 psi) greater than the oil pressure. The boiler fires No. 6 oil, and the temperature of the oil at the burner was approximately 367K (200°F). The nominal oil pressure at top load was 0.58 MPa (85 psi). The boiler is outfitted with a tubular air heater to preheat the combustion air.

The test boiler was situated in the main power plant of a chemical process plant and was one of four boilers used for supplying process steam. The NO_x control technology employed at this test site was staged combustion air, which was shown previously to be effective for reducing NO_x emissions from this boiler. Staged combustion was achieved by removing the upper burner (#1) from service. This does not upset the symmetry of the furnace because of the triangular arrangement of the burners. By terminating the fuel flow to the #1 burner and leaving the air register 100 percent open, the excess air to the active burners was reduced to two-thirds of its original value with all burners in service, because the remaining one-third of the air was injected through the out-of-service burner port. When firing with one burner out of service, the maximum steam flow possible was 17.6 MW thermal

output (60,000 lb/hr). The load was restricted to this value by fuel pressure. A maximum fuel pressure of 0.689 MPa (100 psi) was available which, coupled with the oil gun orifices, limited the fuel flow.

2.3 DAILY TEST ACTIVITY

This section describes the daily test activity at Site 2 following the monitor certification tests. The schedule of monitor certification test events is presented in Section 3-1. A schedule of daily events is presented in Table 2-2.

The data from the gaseous analyzers (NO, CO, CO_2, and O_2) were continuously recorded on strip chart recorders. Gaseous data were read five times daily and recorded on the form shown in Figure B-6, Appendix B. These data were subsequently used for verification of the data reduced from the strip charts for analysis. Boiler operating data were recorded periodically by KVB personnel. Daily charts of steam flow for the entire test period were provided by the boiler operators. The strip chart recorders recorded gaseous emissions 24 hours per day, 7 days per week. No control room data were recorded on weekends; however, the technician did calibrate the instruments on the weekend.

Daily tasks consisted of (1) instrument calibration and recording of control room and emissions data; (2) consultation with boiler operators regarding boiler operation in the low NO_x mode; (3) periodic maintenance of instruments and sample system; (4) visual inspection and troubleshooting of the sampling system and instrumentation console; and (5) procuring supplies and equipment for the particulate and Method 7 tests.

TABLE 2-2. SCHEDULE OF DAILY EVENTS - SITE 2

Time	Event
0800	Calibrate (zero and span) gaseous analyzers (NO, CO_2, CO, and O_2). Record gaseous emissions data. Record boiler control room data. Consult with operators concerning boiler operation.
0845	Calibrate opacity monitor.
0900	Perform daily systems checkout.
1000	Calibrate and record gaseous emissions data.
1200	Calibrate and record gaseous emissions data. Record control room data.
1400	Calibrate and record gaseous emissions data.
1600	Calibrate and record gaseous emissions data. Record control room data.
1700	Calibrate analyzers prior to departing plant. Perform visual check of sampling systems and boiler operation. Leave instructions with operators.

SECTION 3.0

TEST RESULTS

This section summarizes the emission and efficiency data collected on the residual-oil-fired boiler. The NO_x control technology employed on this boiler was staged combustion air. The boiler was tested in the as-found condition initially and in the low NO_x mode for 32 days. The boiler fires No. 6 fuel oil. The results presented herein summarize the gaseous and particulate emissions data, efficiency, and present conclusions for the boiler operating under low NO_x conditions for extended duration.

3.1 CONTINUOUS-MONITOR CERTIFICATION TESTS

The continuous monitor described in the previous section was used to measure the boiler gaseous emissions. Following shipment to the test site, the monitoring system was installed and certification tests performed in accordance with Performance Specifications 2 (PS2) and 3 (PS3), 40 CFR 60, Appendix B (reproduced here as Appendix D). This appendix establishes minimum performance specifications that the NO monitoring system must meet in terms of eight parameters: accuracy, calibration error, 2- and 24-hour zero drifts, 2- and 24-hour calibration drifts, response time, and operational period.

The continuous-monitor system was installed and instruments were initially calibrated on March 13, 1979. The following day the monitor performance certification began. A daily event schedule for the certification tests is presented in Table 3-1.

The performance of the continuous monitor is summarized in Table 3-2. Also shown in the table are the monitor specifications extracted from PS2 and PS3. Included in this table is the performance of the CO analyzers which is

*Performance specifications from 40 CFR 60, Appendix B, reproduced here as Appendix D.

**Instrument has no zero adjustment.

not covered by the performance specification. The CO analyzer is used to monitor the combustion conditions in the boiler since it is a very sensitive indicator of combustion performance. Tables C-1 through C-18, Appendix C, show the performance of each of the analyzers for the certification tests.

The data presented in Table 3-2 show analyzers in the continuous monitor bettered the performance specification values for each parameter for each instrument.

Certified calibration gases were obtained from Scott Environmental Technology Inc. The calibration gases included 50 percent and 90 percent span gases for the NO, CO_2, CO, and O_2 analyzers, and a zero gas. In addition to the certified analysis supplied by the vendor, sample flasks were taken for each calibration gas and sent to an independent laboratory for analysis.

Relative accuracy tests for the NO analyzer were performed as outlined in PS2 using EPA Reference Method 7 (phenoldisulfonic acid [PDS] colorimetric) as the standard. Nine sets of three PDS flasks were collected at one-hour intervals at the beginning and end of the 30-day test period. At the fifteenth day, an abbreviated series of six flasks were taken. All sample flasks were returned to an independent laboratory for analysis. The results of the relative accuracy determination are shown in Tables C-17 and C-18 for the start and end of the 30-day tests. Both tests showed that the NO instrument greatly bettered the accuracy requirements of PS2. The relative accuracy of the Thermo Electron NO analyzer was about 8 percent based on the first test series and about 10.5 percent based on the final test series. The relative accuracy requirement published in PS2 is $\leq$ 20 percent of mean reference value.

3.2 RESIDUAL-OIL-FIRED BOILER TESTS

The continuous monitor was installed by KVB personnel on March 13, 1979, at Site 2, a residual-oil-fired water tube boiler. A single unheated 9.5 mm (3/8-inch) nylon sample line was strung from the duct downstream of the combustion air preheater to the continuous monitor. A single stainless steel filter was installed on the centerline of the duct. Particulate samples were taken from three ports on the side of the duct.

The boiler was initially tested in the as-found condition on March 15, 1979. The boiler load during this test was 16.1 MW thermal input (55,000 lb steam/hr). All burners were in service at this time.

Following the tests in the as-found condition, boiler operation was adjusted, under KVB supervision, to the low NO_x configuration. The top burner in the triangular arrangement was taken out of service. All air registers remained 100 percent open.

Triplicate Method 5 particulate tests were completed after boiler operation in the low NO_x mode stabilized. Triplicate Method 5 measurements under low NO_x operation were also made at the end of the 30-day test period. Method 5 particulate tests were also conducted with all burners in service. During one low NO_x particulate test and one baseline test, samples were collected for POM analysis. The method for collecting this sample was described in paragraph 2.1.3.

Fuel oil samples were collected periodically and submitted to an independent laboratory for analysis. Fuel samples were taken each time a particulate test was made and each time an oil delivery or change of tanks occurred.

A daily summary of the gaseous emissions observations is presented in Table 3-3 for each day of testing. In addition to the strip chart recording of each analyzer, readings were taken five times daily beginning at 0800. Boiler operating data were recorded four times daily and a 24-hour record of steam flow was obtained. A control room data sheet for this test site is included in Appendix B.

3.2.1 Gaseous Emissions

The boiler at Site 2 was tested during a previous EPA-sponsored program (Reference 1). During the previous tests the effect of boiler load on NO_x emissions was determined over a range of thermal output of 11.7 to

*BOOS: Burner out of service

23.1 MW (40,000 to 79,000 lb/hr steam flow). These data are shown in Figure D-1 in Appendix D which shows that the maximum NO_x levels occur at approximately 19.6 MW (67,000 lb/hr steam flow). The maximum NO_x level measured was 245 ppm (3 percent O_2, dry). The NO_x level at 17.6 MW (60,000 lb/hr), the test condition for one burner out of service, was 240 ppm.

During this program, no provision was included for evaluating the effect of various operating parameters on NO_x emissions. Instead, the conditions previously determined to yield low NO_x operation were duplicated as nearly as possible. The boiler was tested in the as-found condition at the initiation of the test program. Since the maximum capacity of the boiler with one burner out of service is approximately 16.4 MW (56,000 lb/hr steam flow) the boiler was tested in the as-found conditions at this load.

The effect of excess oxygen on NO_x emissions is shown in Figure 3-1 for the boiler at Site 2. Excess oxygen was not intentionally varied, but normal operation resulted in some variation in excess oxygen due to operator technique and the lack of sufficient instrumentation and controls to accurately hold a given excess air condition. The lower curve corresponds to operation with one burner out of service (staged combustion air). The upper curve represents the condition where all burners are firing normally. The solid points in the upper curve are at a higher load condition: 19.6 to 21.1 MW (67,000 to 72,000 lb steam/hour). As the previous data showed, operation at higher load resulted in about a 5 ppm increase over the test load condition.

Over the 30-day period during which the test was performed, there were occasions where the demand was greater than the boiler could provide with one burner out of service. The operators then put the third burner back in service. As a result, the 30-day average represents operation in the low NO_x mode except for the periods when steam demand precluded staged combustion.

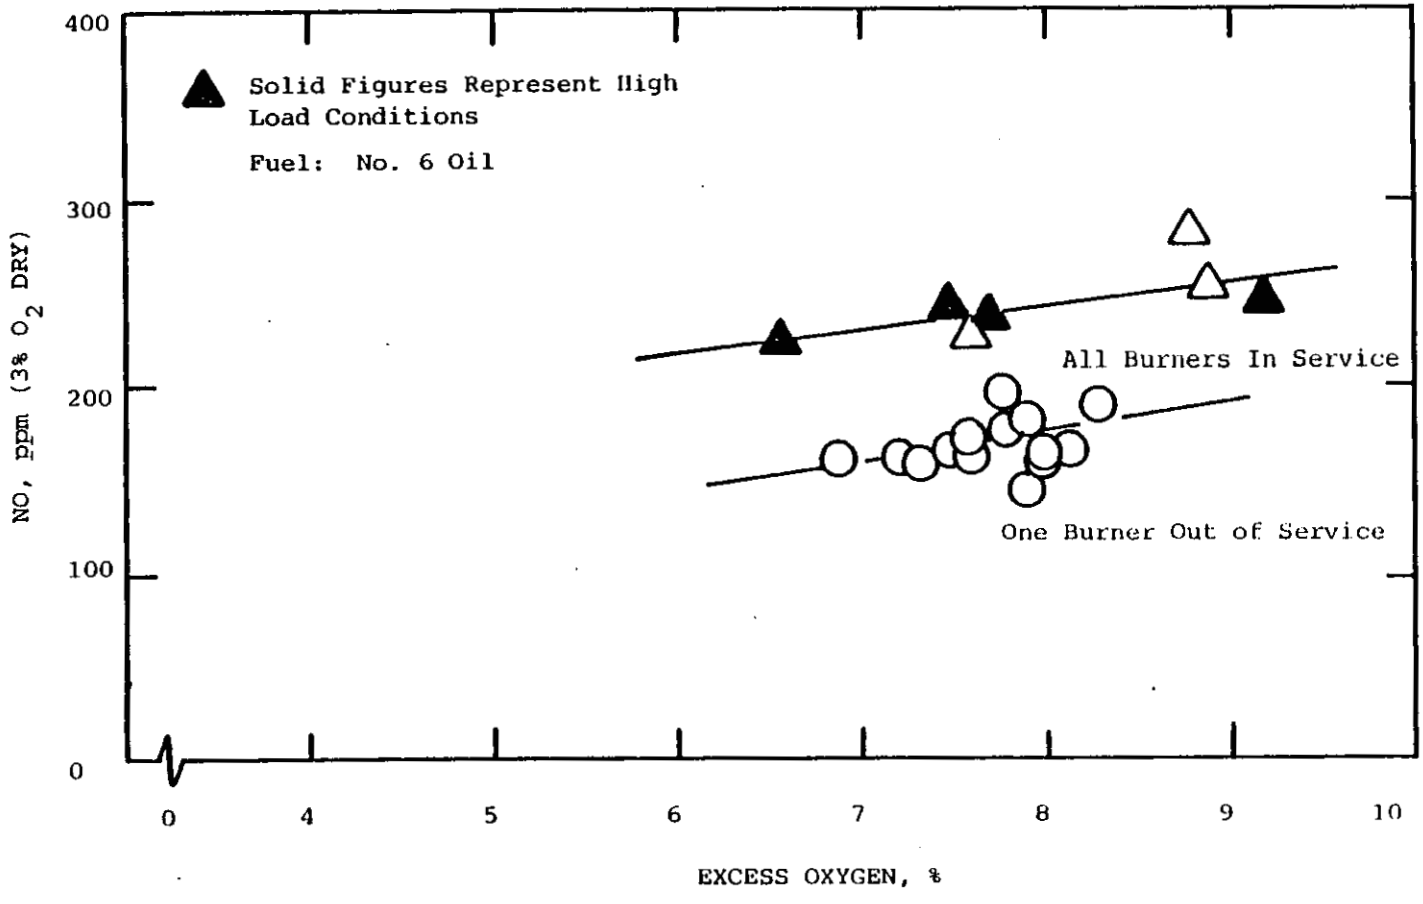

Figure 3-1. The Effect of Excess Oxygen on NO Emissions Site 2 - Residual-Oil-Fired Boiler.

3.2.2 Particulate Emissions

The results of the particulate tests conducted at Site 2 are presented in Table 3-4 for the baseline and low NO_x test conditions. Two of the tests were also used for collecting samples for analysis of polycylic organic matter (POM) by modifying the EPA Method 5 train as described in paragraph 2.1.3. The average particulate loading for baseline conditions, all burners firing, was measured at 25.6 ng/J (0.0594 $lb/10^6$ Btu). The average particulate in the low NO_x condition, one burner out of service, was 37.8 ng/J (0.0878 $lb/10^6$ Btu). The average particulate loading increased 48 percent due to operation in the low NO_x mode.

Visual inspection of the particulate filter in the sampling train showed a much darker particulate deposit, indicating that the particulate contained considerable unburned carbon in the low NO_x mode.

The particulate data for this test site were plotted as a function of excess oxygen in the stack. Figure 3-2 shows particulate loading as a function of stack excess oxygen. The data indicate that particulate loading is not a function of excess oxygen alone. It can also be seen from these data that operation in the low NO_x mode with one burner out of service results in higher particulate loading.

3.2.3 POM Emissions

Samples were collected for analysis of polycyclic organic matter (POM) using a Method 5 sampling train with XAD-2, a POM absorber, inserted. Sample time was extended to two hours to provide a large enough sample for Battelle to analyze. Following the sampling period, the organic resin module was sealed and returned to Battelle Columbus Laboratories for analysis. The sampling probe and glassware were washed with a 50-50 mixture of methylene chloride and methanol per Battelle instructions. The filter and wash were also sent to Battelle following weighing.

These samples were analyzed by capillary-EI GC-MS utilizing a 30M SE-52 column with hydrogen as a carrier gas. All data were collected by single ion monitoring to improve selectivity and sensitivity.

TABLE 3-4. PARTICULATE DATA SUMMARY FOR SITE 2
RESIDUAL-OIL-FIRED BOILER

Test No.	Date 1979	Load MW	Load 10^3 lb/hr	O_2 %	Opacity %	Particulate ng/J	Particulate $lb/10^6$ Btu	Description

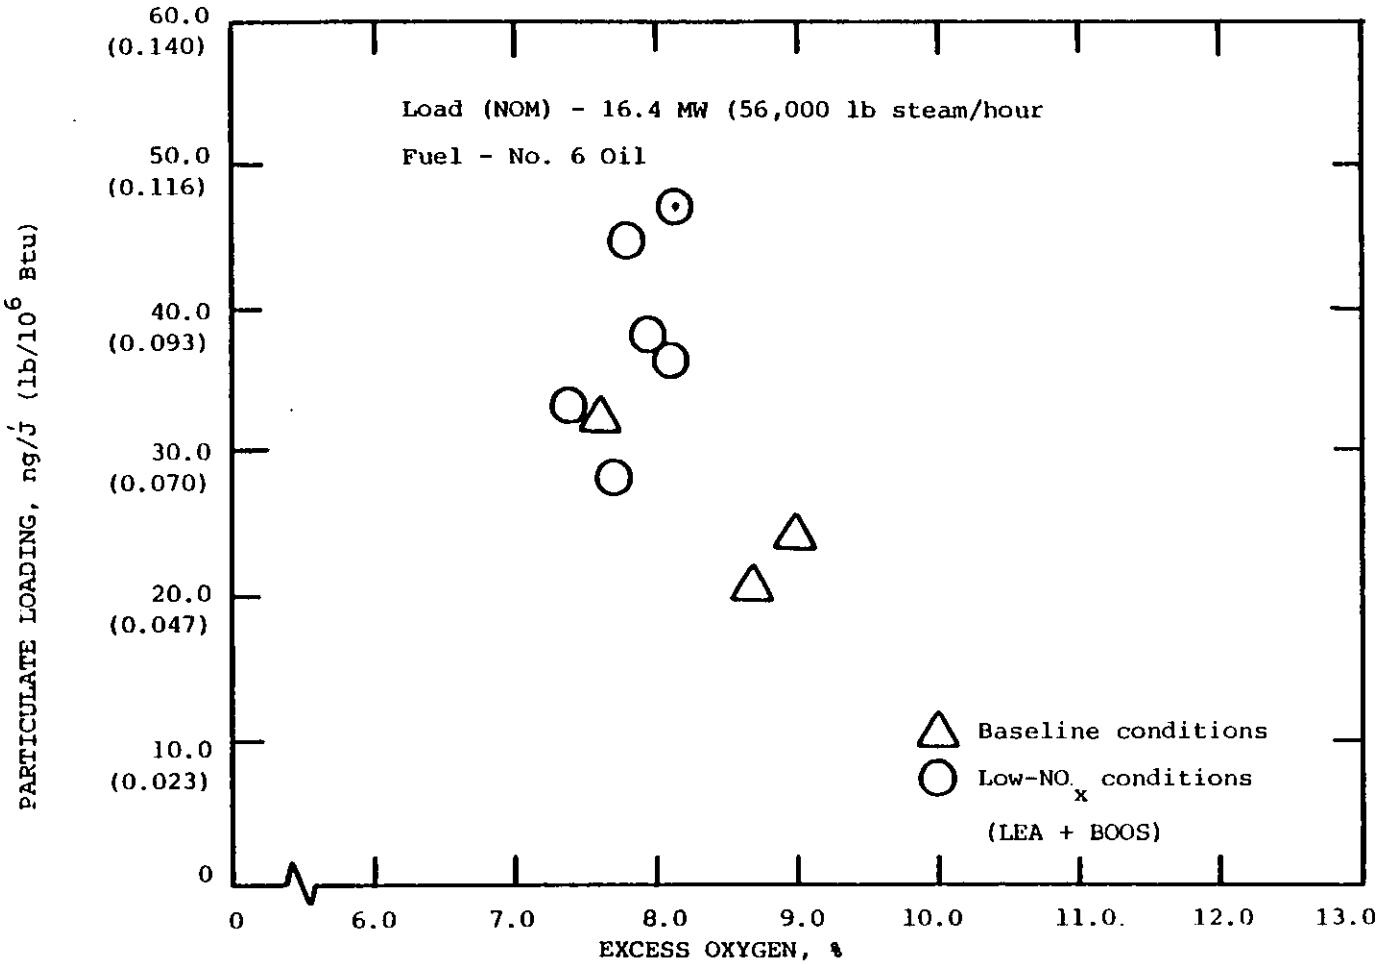

Figure 3-2. Particulate Loading vs. Stack Excess Oxygen for 30-Day Test Location 6017-2

The results of the analyses are presented in µg per total sample. The quantitative detection limit was 0.5 µg; thus samples with POM present at levels lower than this are reported as <0.5 µg (the standard deviation at lower levels was prohibitively high for accurate quantification). Samples reporting POM values of ND (none detected) are at a level of less than 0.1 µg (the approximate qualitative detection limit). The standard deviation on points around 0.5 µg averaged ±20 percent. At levels around 5 µg it averaged ±15 percent, and at levels above 12 µg the standard deviation averaged ±10 percent.

The results of the Battelle analyses are presented in Table 3-5 for the low NO_x and baseline operating conditions. The first three columns present the data for the low NO_x test; the last three columns represent the baseline condition. The XAD-2 module was analyzed separately, with the filter and probe wash samples combined for analysis.

The data indicate a slightly lower (18 to 30 percent) concentration of POM when operating in the low NO_x mode. The only components with significant levels are phenanthrene, anthracene, and methyl anthracenes/phenanthrenes. POM accounted for less than 0.01 percent of the total particulate.

3.2.4 Boiler Efficiency

Boiler efficiency calculations were made for as-found and low NO_x operating conditions. The ASME Abbreviated Efficiency Test method was used to determine the boiler efficiency. This test method is described in Appendix A.

Fuel oil samples were collected during each particulate test and when oil shipments were received or tanks changed. Fuel oil samples were submitted to an independent laboratory for ultimate and heating value analyses. The results of the fuel oil analyses are tabulated in Table 3-6. The data, tabulated chronologically, indicate that oil properties did not change significantly during the test period.

Table 3-7 presents a summary of boiler efficiency measurements made at baseline and low NO_x conditions. The average boiler efficiency under baseline conditions (all burners firing) was 81.9 percent; average efficiency under low NO_x conditions (one burner out of service) was 82.6 percent or an average increase of 0.7 percent.

Average Low NO_x Efficiency $\bar{y}$ = 82.6%

3.2.5 Data Reduction

The gaseous emissions data measured by the analyzers were recorded on strip chart recorders as described earlier. An automatic data logger was ordered but was not available for this 30-day test. The only alternative was manual reduction of strip chart records and punched cards for computer data input as was the case for Site 1. This procedure required a very large manpower effort to produce the data required for analysis.

Strip chart records were collected from the recorders along with copies of the appropriate control room data logs. The recorder charts were reviewed to detect any possible data gaps. In addition, the strip chart records were verified by comparison with measurements recorded by a technician on a two-hour basis.

A tabulation of 15-minute averages was compiled for the entire test period. After the data were compiled, they were spot checked and edited to detect obvious errors and anomalies. The data were then keypunched on cards for input to the computer. Figure 3-3 shows an example of the list of 15-minute averages. The entire list of 15-minute averages is presented in Appendix F.

After data editing was completed, 24-hour averages were calculated For an average to be valid, at least 75 percent of the 15-minute points in that interval had to be valid. Figure 3-4 shows a summary of the 24-hour averages for the 30-day test at Site 1.

A statistical summary was prepared to determine the following parameters for the 24-hour averages: mean, standard deviation, maximum, minimum, range, and average deviation. These parameters were calculated assuming the data were normally distributed. The 24-hour averages were tabulated in ascending order and divided into 10 groups. A frequency histogram was then prepared. Table 3-8 presents the frequency distribution of the 24 hour averages of NO emissions of all data. These data were then plotted to determine the distribution. When the data were plotted on normal probability paper (Figure 3-5) it was apparent that the data were not normally

$\bar{x}$ (geometric median) = 110 ng/J

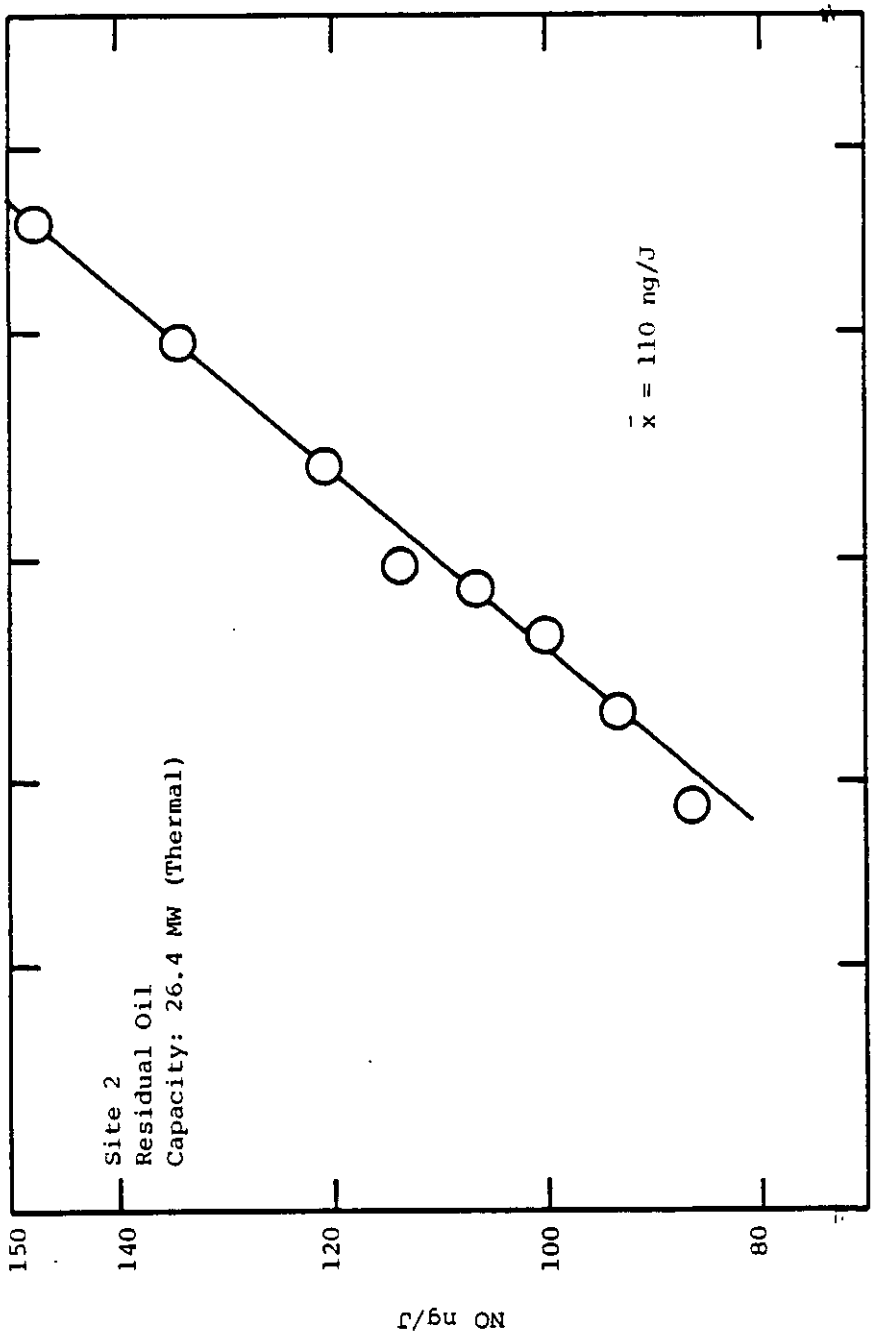

Figure 3-5. Normal-probability plot of 24-hour averages of NO emissions from a residual oil fired boiler.

distributed. Further analysis indicated that the data were log-normally distributed. The data and log sheets were reviewed to separate the emissions data into two groups corresponding to low NO_x firing conditions (one burner out of service) and normal operating conditions. Table 3-9 presents the frequency distribution of the boiler NO emissions while operating in the SCA condition. Table 3-10 shows the frequency distribution with the boiler operating in the normal mode. A log-normal plot of NO emissions is presented as Figure 3-6 for the residual oil fired boiler at Site 2 under low NO_x operating conditions. The graph shown in Figure 3-7 illustrates the performance of the residual oil fired boiler with all burners in service based on the 24-hour averages. The mean NO emission rate is 100 ng/J with a geometric dispersion of 1.12 while operating with SCA. The NO emission rate from the boiler while operating in the normal mode (all burners firing) was determined to be 130 ng/J with a geometric dispersion of 1.11.

A daily plot of the NO emissions is shown in Figure 3-8. This plot shows high levels in NO emissions when all burners are firing a large fraction of the day or when the excess O_2 level is high. Figure 3-9 presents a daily plot of excess O_2. High values of excess O_2 correspond to high NO emission rates, even if a burner is out of service. The high excess O_2 levels generally correspond to week-ends where KVB personnel were not on hand to advise the operational personnel on the excess air condition.

Staged combustion as a NO_x control technique resulted in a 23 percent reduction from the baseline value of 130 ng/J. Under low NO_x operation (SCA), 99 percent of the values were less than 130 ng/J. Under normal operating conditions, 99 percent of the values were less than 170 ng/J.

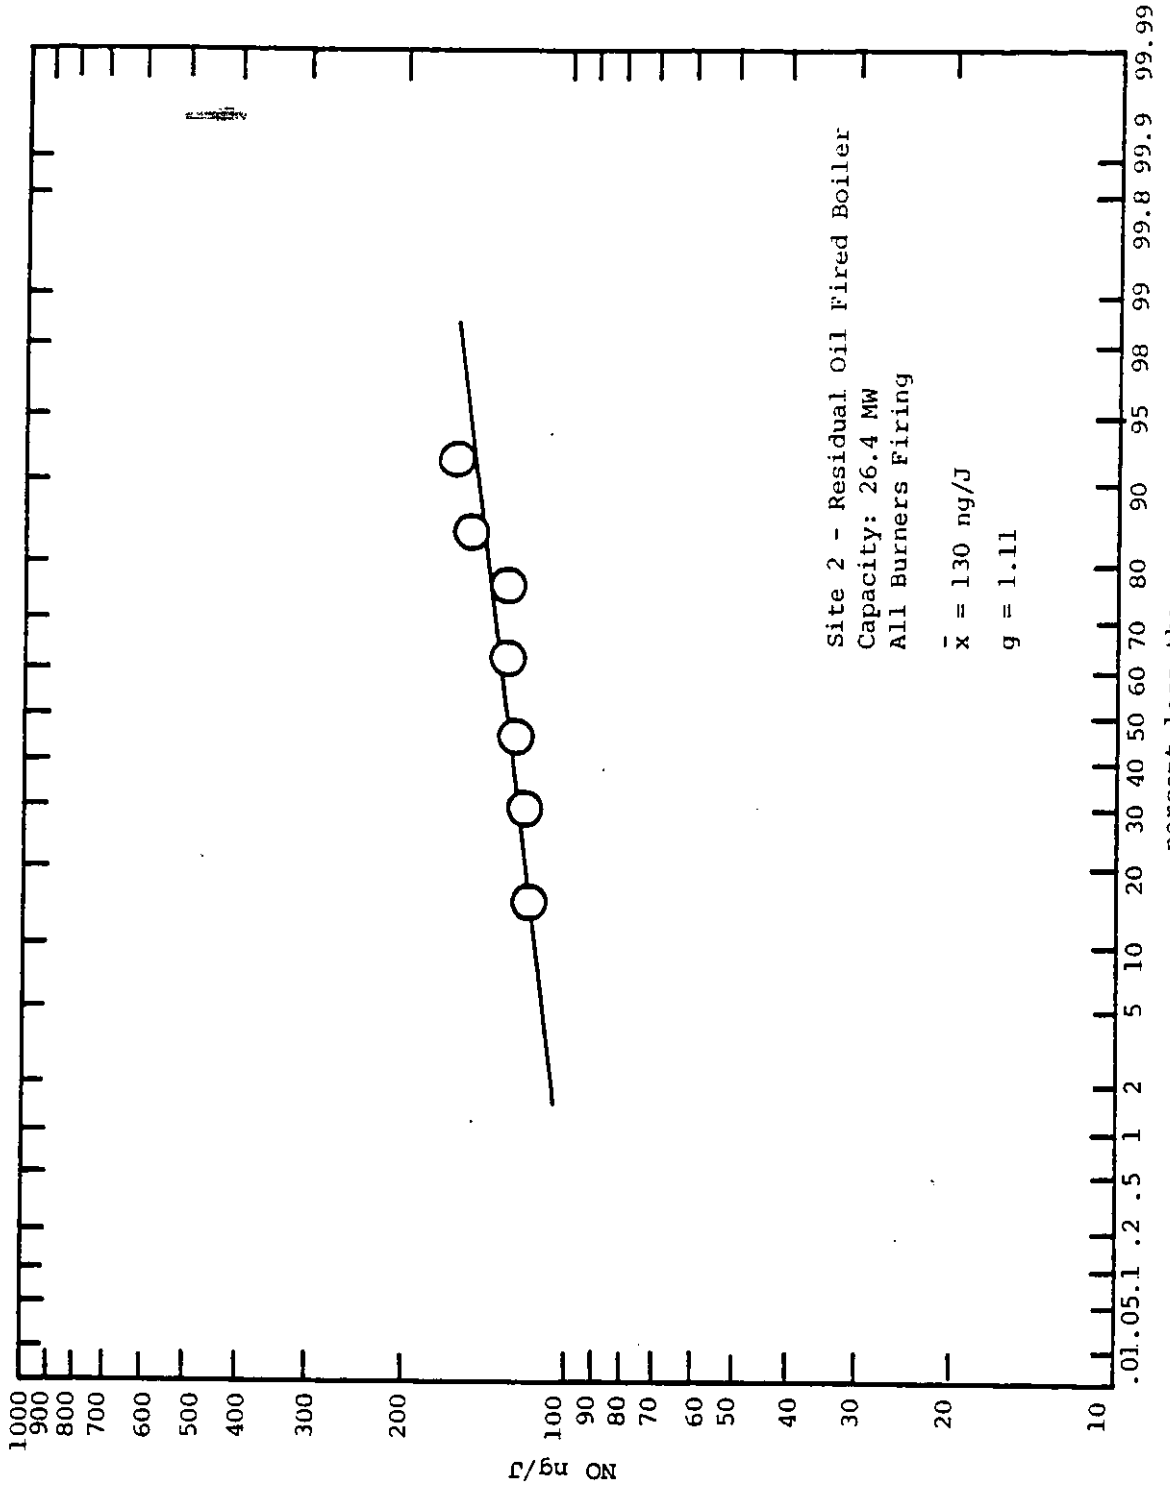

Figure 3-7. Log-Probability Plot of 24-Hour Averages of NO Emissions from a Residual Oil Fired Boiler under normal operation.

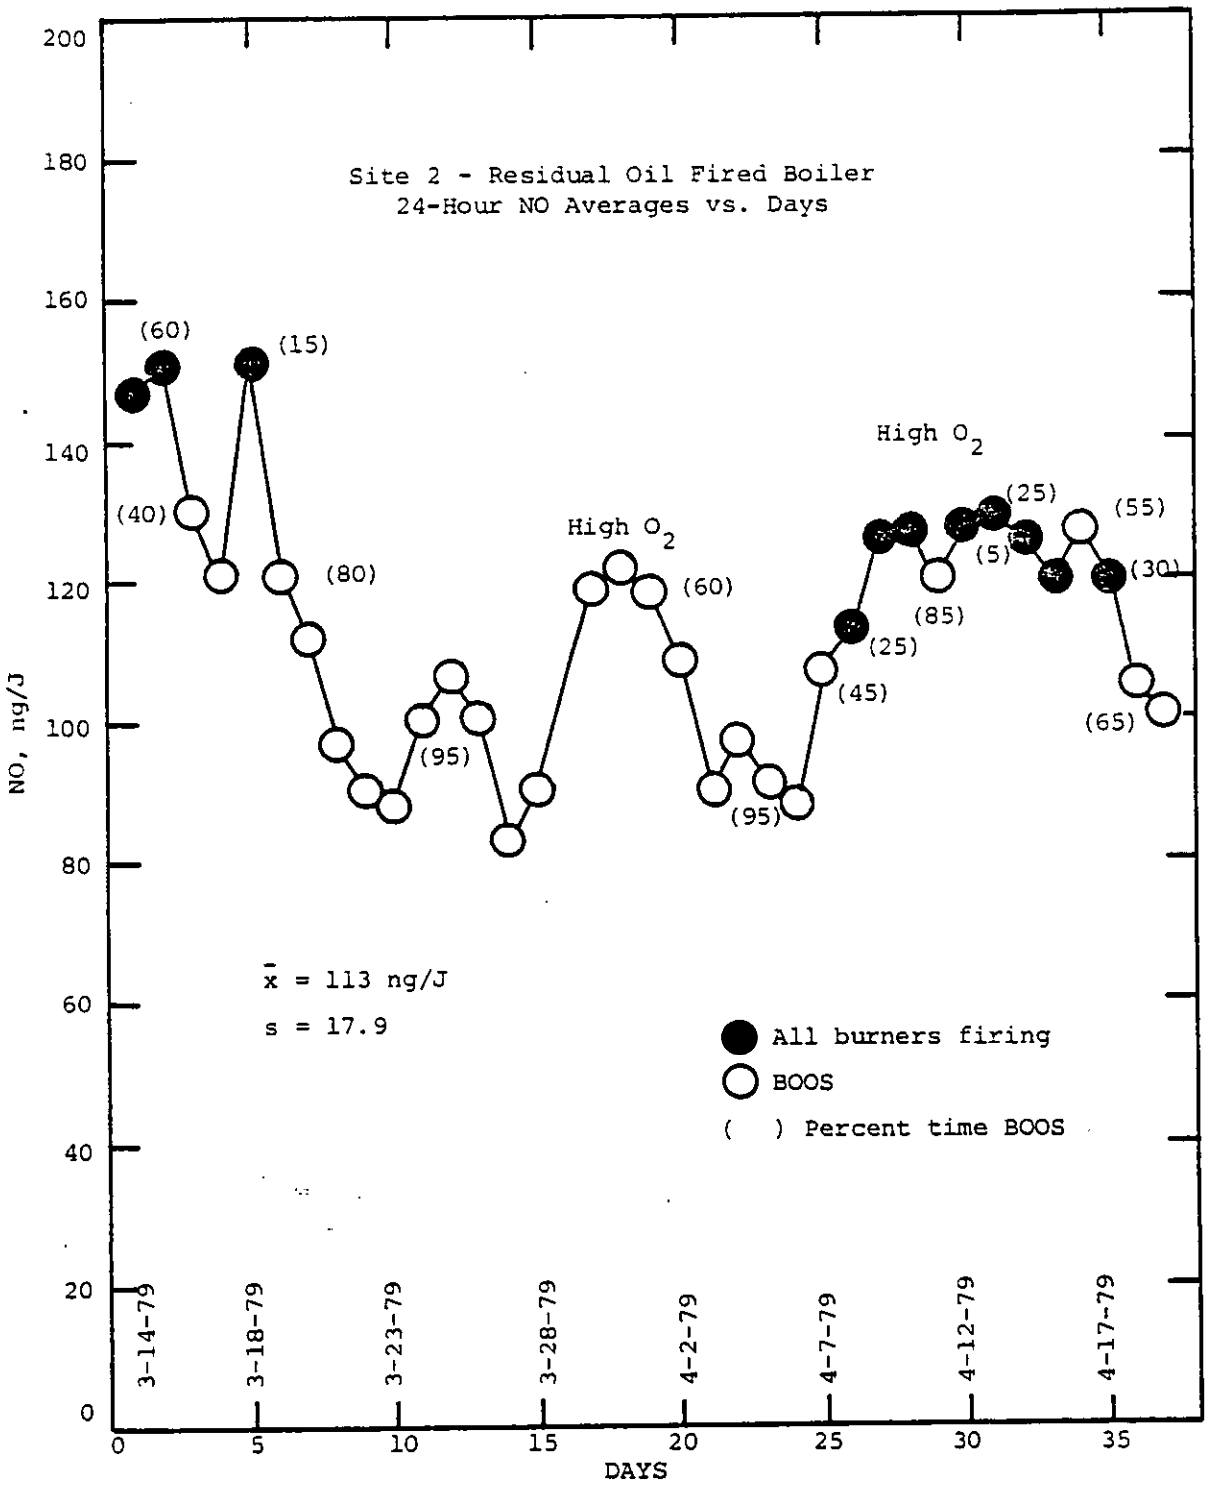

Figure 3-8. Daily Plot of NO Emissions

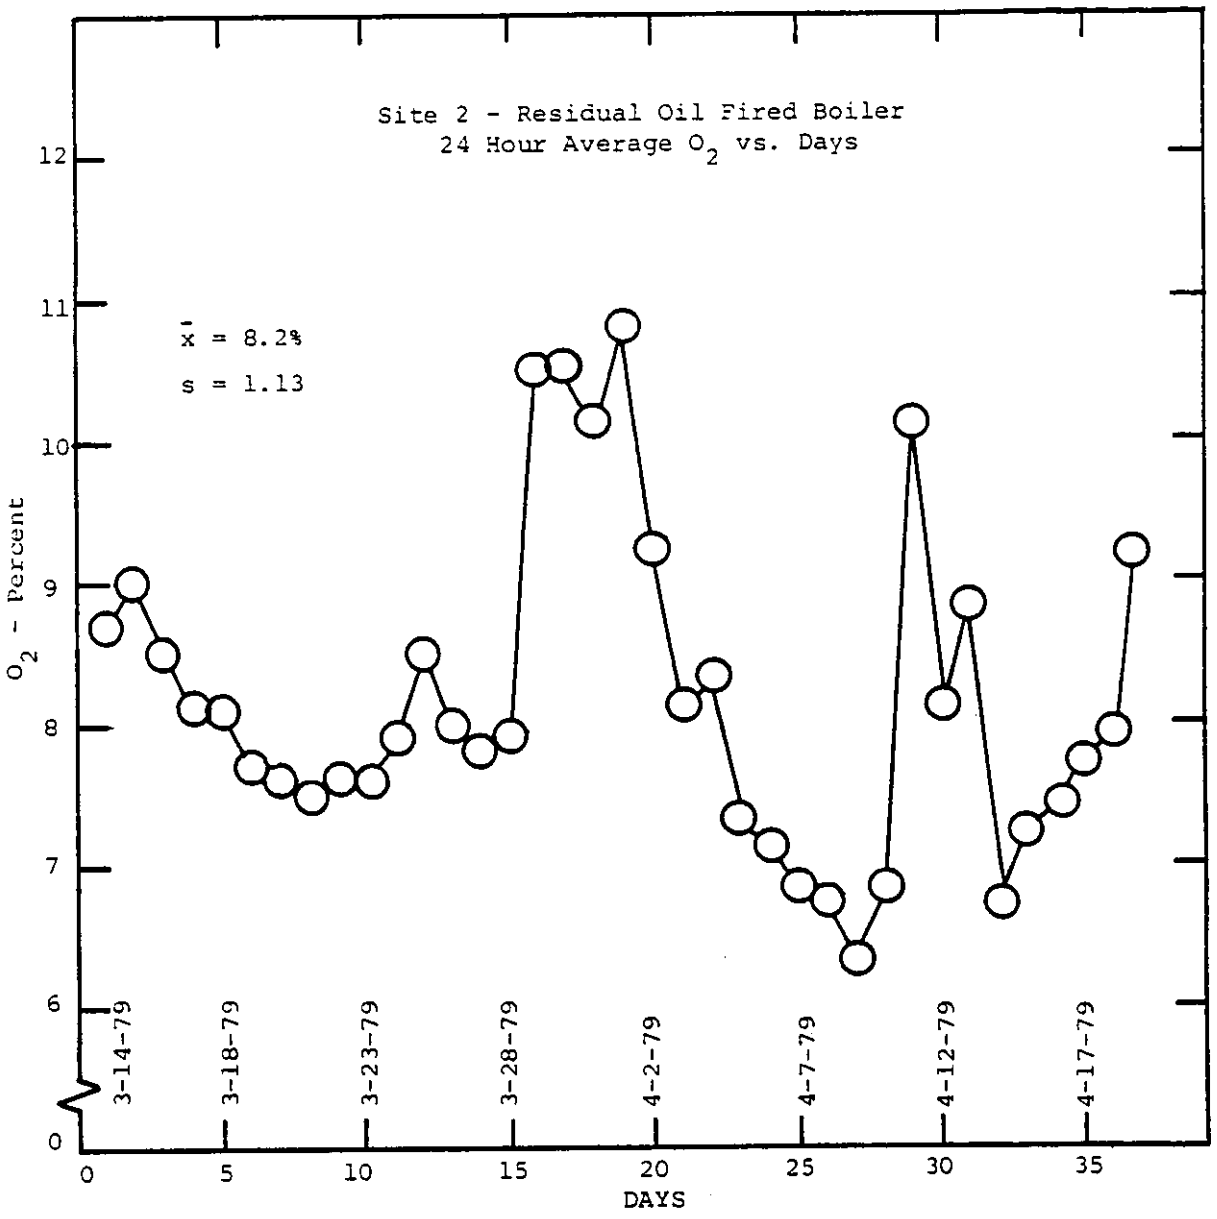

Figure 3-9. Daily Plot of Excess O_2

Emission factors for the residual oil fired boiler were calculated using the procedure set forth in 40CFR60, Subpart D. The NO emission factor (dry basis) was calculated using the following equation:

$$D = C_d F_d \frac{20.9}{20.9 - \% O_{2_d}}$$

Where E = Pollutant emission rate, ng/J (lb/million Btu)

C_d = NO concentration, ng/scm (lb/scf)

F_d = Stoichiometric conversion factor, 2.47×10^{-7} dscm/J (9,190 dscf/million Btu), for residual oil

O_{2_d} = Oxygen concentration, percent by volume, dry

The conversion of measured NO values (ppmv) to ng/scm is made by multiplying by 1.912×10^{6}. To convert from ppm to lb/scf, multiply by 1.19×10^{-7}.

NO_x emissions were measured as NO and the NO_x emission rates reported herein are calculated based on the molecular weight of NO_2.

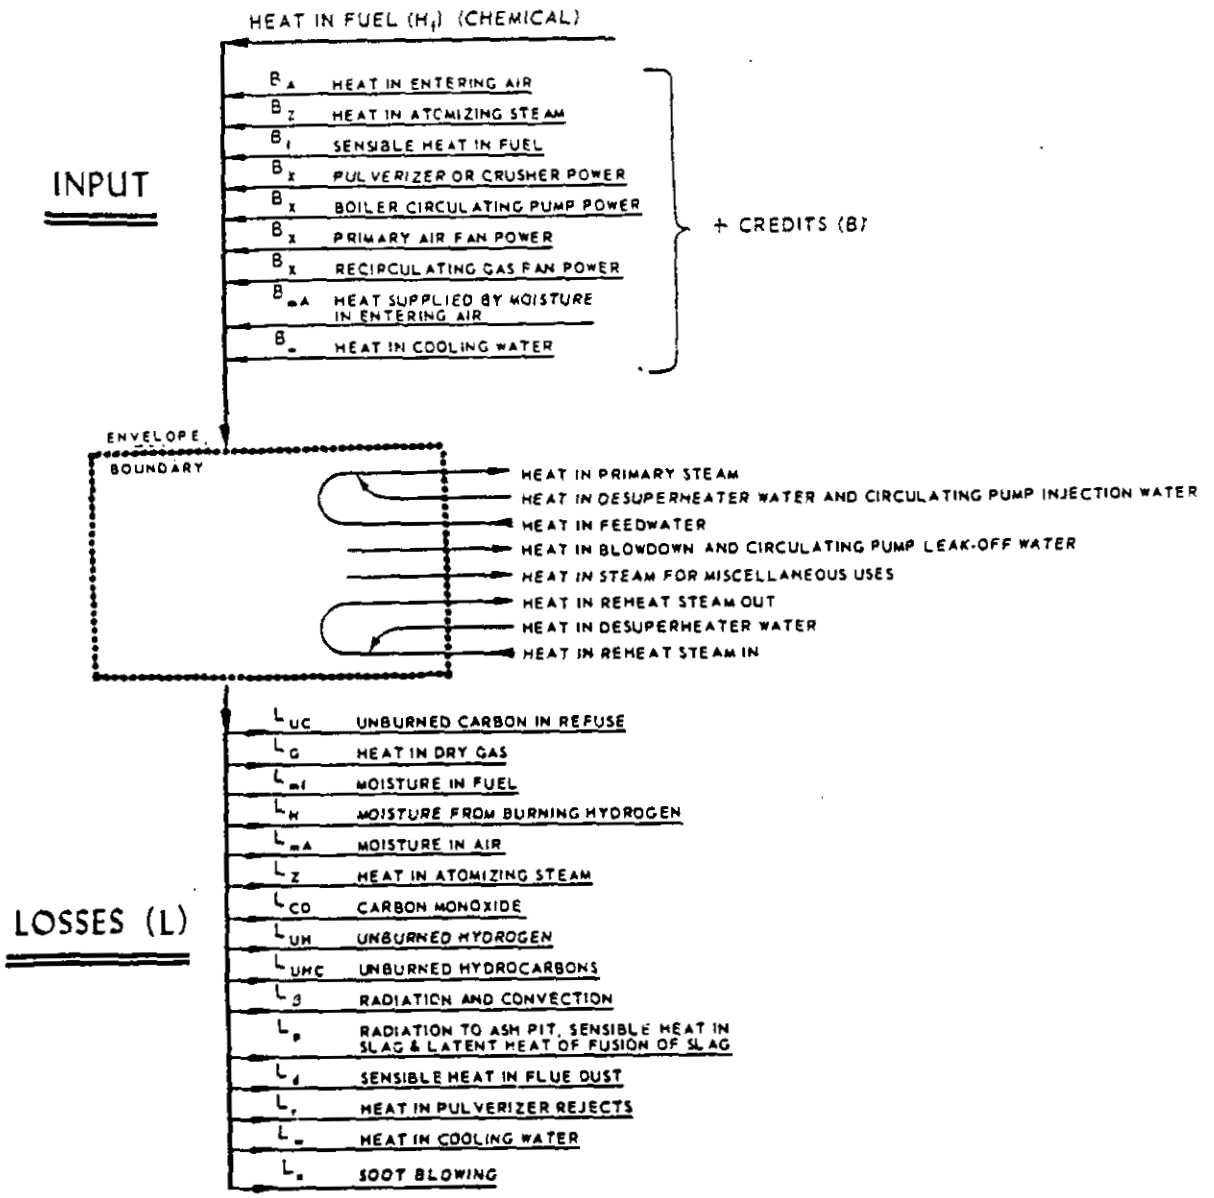
APPENDIX A

EFFICIENCY MEASUREMENTS

EFFICIENCY

Unit efficiencies for boilers are calculated and reported according to the ASME Power Test Codes for Steam Generation Units, PTC 4.1-1965. These codes present instructions for two acceptable methods of determining thermal efficiency. One method is the direct measurement of input and output and requires the accurate measurement of the quantity and high-heating value of the fuel, heat credits, and the heat absorbed by the working fluids. The second method involves the direct measurements of heat losses and is referred to as the heat loss method. This method requires the determination of losses, heat credits, and ultimate analysis and high-heat value of the fuel. Some of the major heat losses include losses due to heat in dry flue gas, losses due to fuel moisture content, losses due to combustible material in refuse and flue gas, and radiation losses. Heat credits are defined as those amounts added to the process in forms other than the chemical heat in the fuel "as fired." These include quantities such as sensible heat in the fuel, heat in the combustion air, and heat from power conversion in a pulverizer or fan. The relationships between input, output, credits, and losses for a steam generator are illustrated in Figure A-1.

KVB's experience has shown the heat-loss efficiency determination method to be the most reliable when working with industrial boilers. Accurate fuel input measurements are rarely possible on industrial boilers due to the lack of adequate instrumentation, thus making the input-output method undesirable. The accuracy of the efficiency based on the heat loss method is determined primarily by the accuracy of the flue gas temperature measurement immediately following the last heat removal station, the stack gas excess O_2 level, the fuel analysis, the ambient temperature, and proper identification of the combustion device external surfaces (for radiation losses). Determination of the radiation and other associated losses may appear to be a rather imposing calculation, but in practice it can be accomplished by utilizing standard efficiency calculation procedures. Inaccuracies in determining efficiency occasionally occur even with the heat



OUTPUT = INPUT − LOSSES

DEFINITION: EFFICIENCY (PERCENT) = η_g (%) = $\frac{\text{OUTPUT}}{\text{INPUT}} \times 100 = \frac{\text{INPUT} - L}{H_f + B} \times 100$

HEAT BALANCE: $H_f + B$ = OUTPUT + L OR η_g (%) = $\left[1 - \frac{L}{H_f + B}\right] \times 100$

Figure A-1. Heat balance of steam generator.

loss method primarily because of out-of-calibration unit instrumentation such as the stack gas exit temperature. However, this problem has been resolved by KVB test engineers through the use of portable instrumentation and separate temperature readings.

The abbreviated efficiency test procedure which considers only the major losses and the chemical heat in the fuel as input will be followed. Tables A-1 and A-2 are the ASME Test Forms for Abbreviated Efficiency Tests on steam generators which exemplify the type of forms to be used for recording the necessary data and performing the required calculations.

KVB has developed a program for the HP-67 calculator which will provide the heat loss efficiency from the stack data. Figure A-2 shows the HP-67 keyed calculation sheet for calculating efficiency by the ASME Heat Loss Method.

Test No._____ Date_____ Location_____ Unit No._____ Fuel_____

(Turn Calculator Off and Then On. Load Program Card.)

A. FROM FUEL ANALYSIS:
Wt. % in as-fired fuel: C _____ (A1: STO 0)%, Moisture _____ (A2: STO 1)%, H _____ (A3: STO 2)%, S _____ (A4: STO 3)%
High heating value of fuel as-fired _____ (A5: STO 4) Btu/lb

B. FROM FLUE GAS ANALYSIS:
Volume % in flue gas of: O_2 _____ (B1: STO 5)%, CO_2 _____ (B2: STO 6)%, CO _____ (B3: STO 7)%

C. FROM REFUSE (FLY ASH AND ASH PIT) ANALYSIS:
C1. Fraction of dry refuse in fuel _____ (STO 8) lbs dry refuse/lb as-fired fuel
C2. Heating value of dry refuse (weighted average) _____ (STO 9) Btu/lb dry refuse
C3. Wt. % of combustibles in refuse _____ (f P ≷ S)(STO 4)(f P ≷ S) %

D. MEASURED TEMPERATURES
D1. Gas temp. leaving boiler, econ. or air heater _____ (STO A) °F
D2. Comb. air temp. _____ (STO B) °F

E. FROM STEAM TABLES:
E1. Enthalpy: $H_2O(g)$ at temp. D1 & 1 psia _____ (STO C) Btu/lb
E2. Enthalpy: $H_2O(l)$ at comb. air temp. _____ (STO D) Btu/lb

F. FROM ABMA STANDARD RADIATION LOSS CHART (UNLESS MEASURED):
F1. Heat loss due to radiation _____ (STO E)% of gross heat input

G. FROM UNIT SPECIFICATIONS (if available, otherwise enter 0):
G1. Unmeasured losses _____ (f P ≷ S)(STO 0)(f P ≷ S) % of gross heat input

1. Excess Air $\approx \dfrac{100\ (2B1 - B3)}{0.5364(100 - B1 - B2) - (2B1 - B3)}$ (A)_____ %

2. (Optional) Pounds dry gas per pound of fuel =

$$\frac{B1 + 4B2 + 700}{3(B2 + B3)} \times \left[\frac{A1}{100} - \frac{C1 \times C2}{14500\left(1 - \frac{C3}{100}\right)} + \frac{3A4}{800}\right]$$

(R/S)_____ lbs dry gas/lb as-fired fuel

Heat Losses	% of Gross Heat Input	(Optional) Btu/lb as-fired fuel*
3. Due to dry gas = $\frac{24 \times EQ.2 \times (D1 - D2)}{A5}$	(B)_____	(R/S)_____
4. Due to moisture in fuel = $\frac{A2 \times (E1 - E2)}{A5}$	(C)_____	(R/S)_____
5. Due to H_2O from combustion of H_2 = $\frac{9 \times A3(E1 - E2)}{A5}$	(D)_____	(R/S)_____
6. Due to combustibles in refuse = $\frac{100 \times C1 \times C2}{A5}$	(E)_____	(R/S)_____
7. Total Losses = Sum of calculated losses + F1 + G1	(f a)_____	(R/S)_____
8. Efficiency = 100 - Total Losses	(f b)_____	

*Calculated as percent of gross heat input x A5 ÷ 100

APPENDIX B

DATA RECORDING FORMATS

DOCUMENTATION OF RESULTS

Field Measurements

During testing, two sets of measurements are recorded: 1) control room data which indicate the operating condition of the device and 2) emissions data that are the readouts of the individual analyzers.

The concentration of nitric oxide (NO), carbon dioxide (CO_2), carbon monoxide (CO), and oxygen (O_2) are measured and recorded. The concentration of these species are measured and displayed continuously by analyzers and strip chart recorders mounted in a console. The strip chart recordings are retained for future reference. Opacity, particulate loading, and POM concentration are measured at the sampling port and the measurements recorded on data sheets.

A number of data sheets have been developed for use in field measurements. These data sheets are listed below together with their purpose. An example of each sheet follows.

Figure No.	Title	Purpose
B-1	Thirty-Day Field Test Data Sheets	Record control room data
B-2	Gaseous Emissions Data	Record Gaseous Emissions Analyzer data
B-3	Nozzle Size, Q_m and ΔH Calculations	Calculate nozzle size, flow rate, and ΔH for Method 5 Test
B-4	Response Time for Continuous Instruments	Continuous monitor certification
B-5	Zero and Calibration Drift (24 hr)	Continuous monitor certification
B-6	Zero and Calibration Drift (2 hr)	Continuous monitor certification
B-7	Accuracy Determination (NOx)	Continuous monitor certification
B-8	Calibration Error Determination	Continuous monitor certification

Figure No.	Title	Purpose
B-9	Analysis of Calibration Gas Mixture	Continuous monitor certification
B-10	Particulate Calculation Sheet	Calculate weight of solid particulate catch
B-11	Stack Data	Record volumes, temperatures, pressures of Method 5 control unit.
B-12	Particulate Emission Caculations	Calculate particulate emmision factors
B-13	Velocity Traverse	Record temperature and velocity profile of stack
B-14	Liquid or Solid Fuel Calculation	Calculate stoichiometric properties of fuel

APPENDIX D

CONTINUOUS MONITOR PERFORMANCE SPECIFICATIONS

PERFORMANCE SPECIFICATION 2—PERFORMANCE SPECIFICATIONS AND SPECIFICATION TEST PROCEDURES FOR MONITORS OF SO_2 AND NO_x FROM STATIONARY SOURCES

1. Principle and Applicability.

1.1 Principle. The concentration of sulfur dioxide or oxides of nitrogen pollutants in stack emissions is measured by a continuously operating emission measurement system. Concurrent with operation of the continuous monitoring system, the pollutant concentrations are also measured with *reference* methods (Appendix A). An average of the continuous monitoring system data is computed for each reference method testing period and compared to determine the relative accuracy of the continuous monitoring system. Other tests of the continuous monitoring system are also performed to determine calibration error, drift, and response characteristics of the system.

1.2 Applicability. This performance specification is applicable to evaluation of continuous monitoring systems for measurement of nitrogen oxides or sulfur dioxide pollutants. These specifications contain test procedures, installation requirements, and data computation procedures for evaluating the acceptability of the continuous monitoring systems.

2. Apparatus.

2.1 Calibration Gas Mixtures. Mixtures of known concentrations of pollutant gas in a diluent gas shall be prepared. The pollutant gas shall be *sulfur dioxide* or the appropriate oxide(s) of nitrogen specified by paragraph 6 and within subparts. For sulfur dioxide gas mixtures, the diluent gas may be air or nitrogen. For nitric oxide (NO) gas mixtures, the diluent gas shall be oxygen-free (<10 ppm) nitrogen, and for nitrogen dioxide (NO_2) gas mixtures the diluent gas shall be air. Concentrations of approximately 50 percent and 90 percent of span are required. The 90 percent gas mixture is used to set and to check the span and is referred to as the span gas.

2.2 Zero Gas. A gas certified by the manufacturer to contain less than 1 ppm of the pollutant gas or ambient air may be used.

2.3 Equipment for measurement of the pollutant gas concentration using the reference method specified in the applicable standard.

2.4 Data Recorder. Analog chart recorder or other suitable device with input voltage range compatible with analyzer system output. The resolution of the recorder's data output shall be sufficient to allow completion of the test procedures within this specification.

2.5 Continuous monitoring system for SO_2 or NO_x pollutants as applicable.

3. Definitions.

3.1 Continuous Monitoring System. The total equipment required for the determination of a pollutant gas concentration in a source effluent. Continuous monitoring systems consist of major subsystems as follows:

3.1.1 Sampling Interface. That portion of an extractive continuous monitoring system that performs one or more of the following operations: Acquisition, transportation, and conditioning of a sample of the source effluent or that portion of an in-situ continuous monitoring system that protects the analyzer from the effluent.

3.1.2 Analyzer. That portion of the continuous monitoring system which senses the pollutant gas and generates a signal output that is a function of the pollutant concentration.

3.1.3 Data Recorder. That portion of the continuous monitoring system that provides a permanent record of the output signal in terms of concentration units.

3.2 Span. The value of pollutant concentration at which the continuous monitoring system is set to produce the maximum data display output. The span shall be set at the concentration specified in each applicable subpart.

3.3 Accuracy (*Relative*). The degree of correctness with which the continuous monitoring system yields the value of gas concentration of a sample relative to the value given by a defined reference method. This accuracy is expressed in terms of error, which is the difference between the paired concentration measurements expressed as a percentage of the mean reference value.

3.4 Calibration Error. The difference between the pollutant concentration indicated by the continuous monitoring system and the known concentration of the test gas mixture.

3.5 Zero Drift. The change in the continuous monitoring system output over a stated period of time of normal continuous operation when the pollutant concentration at the time for the measurements is zero.

3.6 Calibration Drift. The change in the continuous monitoring system output over a stated time period of normal continuous operations when the pollutant concentration at the *time of* the measurements is the same known upscale value.

3.7 Response Time. The time interval from a step change in pollutant concentration at the input to the continuous monitoring system to the time at which 95 percent of the corresponding final value is reached as displayed on the continuous monitoring system data recorder.

3.8 Operational Period. A minimum period of time over which a measurement system is expected to operate within certain performance specifications without unscheduled maintenance, repair, or adjustment.

3.9 Stratification. A condition identified by a difference in excess of 10 percent between the average concentration in the duct or stack and the concentration at any point more than 1.0 meter from the duct or stack wall.

4. Installation Specifications. Pollutant continuous monitoring systems (SO_2 and NO_x) shall be installed at a sampling location where measurements can be made which are directly representative (4.1), or which can be corrected so as to be representative (4.2) of the total emissions from the affected

facility. Conformance with this requirement shall be accomplished as follows:

4.1 Effluent gases may be assumed to be nonstratified if a sampling location eight or more stack diameters (equivalent diameters) downstream of any air in-leakage is selected. This assumption and data correction procedures under paragraph 4.2.1 may not be applied to sampling locations upstream of an air preheater in a steam generating facility under Subpart D of this part. For sampling locations where effluent gases are either demonstrated (4.3) or may be assumed to be nonstratified (eight diameters), a point (extractive systems) or path (in-situ systems) of average concentration may be monitored.

4.2 For sampling locations where effluent gases cannot be assumed to be nonstratified (less than eight diameters) or have been shown under paragraph 4.3 to be stratified, results obtained must be consistently representative (e.g. a point of average concentration may shift with load changes) or the data generated by sampling at a point (extractive systems) or across a path (in-situ systems) must be corrected (4.2.1 and 4.2.2) so as to be representative of the total emissions from the affected facility. Conformance with this requirement may be accomplished in either of the following ways:

4.2.1 Installation of a diluent continuous monitoring system (O_2 or CO_2 as applicable) in accordance with the procedures under paragraph 4.2 of Performance Specification 3 of this appendix. If the pollutant and diluent monitoring systems are not of the same type (both extractive or both in-situ), the extractive system must use a multipoint probe.

4.2.2 Installation of extractive pollutant monitoring systems using multipoint sampling probes or in-situ pollutant monitoring systems that sample or view emissions which are consistently representative of the total emissions for the entire cross section. The Administrator may require data to be submitted to demonstrate that the emissions sampled or viewed are consistently representative for several typical facility process operating conditions.

4.3 The owner or operator may perform a traverse to characterize any stratification of effluent gases that might exist in a stack or duct. If no stratification is present, sampling procedures under paragraph 4.1 may be applied even though the eight diameter criteria is not met.

4.4 When single point sampling probes for extractive systems are installed within the stack or duct under paragraphs 4.1 and 4.2.1, the sample may not be extracted at any point less than 1.0 meter from the stack or duct wall. Multipoint sampling probes installed under paragraph 4.2.2 may be located at any points necessary to obtain consistently representative samples.

5. Continuous Monitoring System Performance Specifications.

The continuous monitoring system shall meet the performance specifications in Table 2-1 to be considered acceptable under this method.

TABLE 2-1.—*Performance specifications*

Parameter	Specification
1. Accuracy [1]	≤20 pct of the mean value of the reference method test data.
2. Calibration error [1]	≤ 5 pct of each (50 pct, 90 pct) calibration gas mixture value.
3. Zero drift (2 h) [1]	2 pct of span
4. Zero drift (24 h) [1]	Do.
5. Calibration drift (2 h) [1]	Do.
6. Calibration drift (24 h) [1]	2.5 pct. of span
7. Response time	15 min maximum.
8. Operational period	168 h minimum.

[1] Expressed as sum of absolute mean value plus 95 pct confidence interval of a series of tests.

6. Performance Specification Test Procedures. The following test procedures shall be used to determine conformance with the requirements of paragraph 5. For NO_x analyzers that oxidize nitric oxide (NO) to nitrogen dioxide (NO_2), the response time test under paragraph 6.3 of this method shall be performed using nitric oxide (NO) span gas. Other tests for NO_x continuous monitoring systems under paragraphs 6.1 and 6.2 and all tests for sulfur dioxide systems shall be performed using the pollutant span gas specified by each subpart.

6.1 Calibration Error Test Procedure. Set up and calibrate the complete continuous monitoring system according to the manufacturer's written instructions. This may be accomplished either in the laboratory or in the field.

6.1.1 Calibration Gas Analyses. Triplicate analyses of the gas mixtures shall be performed within two weeks prior to use using Reference Methods 6 for SO, and 7 for NO_x. Analyze each calibration gas mixture (50%, 90%) and record the results on the example sheet shown in Figure 2-1. Each sample test result must be within 20 percent of the averaged result or the tests shall be repeated. This step may be omitted for non-extractive monitors where dynamic calibration gas mixtures are not used (6.1.2).

6.1.2 Calibration Error Test Procedure. *Make a total of 15 nonconsecutive measurements* by alternately using zero gas and each calibration gas mixture/concentration (e.g., 0%, 50%, 0%, 90%, 50%, 90%, 50%, 0%, etc.). For nonextractive continuous monitoring systems, this test procedure may be performed by using two or more calibration gas

cells whose concentrations are certified by the manufacturer to be functionally equivalent to these gas concentrations. Convert the continuous monitoring system output readings to ppm and record the results on the example sheet shown in Figure 2-2.

6.2 Field Test for Accuracy (Relative), Zero Drift, and Calibration Drift. Install and operate the continuous monitoring system in accordance with the manufacturer's written instructions and drawings as follows:

6.2.1 Conditioning Period. Offset the zero setting at least 10 percent of the span so that negative zero drift can be quantified. Operate the system for an initial 168-hour conditioning period in normal operating manner.

6.2.2 Operational Test Period. Operate the continuous monitoring system for an additional 168-hour period retaining the zero offset. The system shall monitor the source effluent at all times except when being zeroed, calibrated, or backpurged.

6.2.2.1 Field Test for Accuracy (Relative). For continuous monitoring systems employing extractive sampling, the probe tip for the continuous monitoring system and the probe tip for the Reference Method sampling train should be placed at adjacent locations in the duct. For NO_x continuous monitoring systems, make 27 NO_x concentration measurements, divided into nine sets, using the applicable reference method. No more than one set of tests, consisting of three individual measurements, shall be performed in any one hour. All individual measurements of each set shall be performed concurrently, or within a three-minute interval and the results averaged. For SO_2 continuous monitoring systems, make nine SO_2 concentration measurements using the applicable reference method. No more than one measurement shall be performed in any one hour. Record the reference method test data and the continuous monitoring system concentrations on the example data sheet shown in Figure 2-3.

6.2.2.2 Field Test for Zero Drift and Calibration Drift. For extractive systems, determine the values given by zero and span gas pollutant concentrations at two-hour intervals until 15 sets of data are obtained. For nonextractive measurement systems the zero value may be determined by mechanically producing a zero condition that provides a system check of the analyzer internal mirrors and all electronic circuitry including the radiation source and detector assembly or by inserting three or more calibration gas cells and computing the zero point from the upscale measurements. If this latter technique is used, a graph(s) must be retained by the owner or operator for each measurement system that shows the relationship between the upscale measurements and the zero point. The span of the system shall be checked by using a calibration gas cell certified by the manufacturer to be functionally equivalent to 60 percent of span concentration. Record the zero and span measurements (or the computed zero drift) on the example data sheet shown in Figure 2-4. The two-hour periods over which measurements are conducted need not be consecutive but may not overlap. All measurements required under this paragraph may be conducted concurrent with tests under paragraph 6.2.2.1.

6.2.2.3 Adjustments. Zero and calibration corrections and adjustments are allowed only at 24-hour intervals or at such shorter intervals as the manufacturer's written instructions specify. Automatic corrections made by the measurement system without operator intervention or initiation are allowable at any time. During the entire 168-hour operational test period, record on the example sheet shown in Figure 2-5 the values given by zero and span gas pollutant concentrations before and after adjustment at 24-hour intervals.

6.3 Field Test for Response Time.

6.3.1 Scope of Test. Use the entire continuous monitoring system as installed, including sample transport lines if used. Flow rates, line diameters, pumping rates, pressures (do not allow the pressurized calibration gas to change the normal operating pressure in the sample line), etc., shall be at the nominal values for normal operation as specified in the manufacturer's written instructions. If the analyzer is used to sample more than one pollutant source (stack), repeat this test for each sampling point.

6.3.2 Response Time Test Procedure. Introduce zero gas into the continuous monitoring system sampling interface or as close to the sampling interface as possible. When the system output reading has stabilized, switch quickly to a known concentration of pollutant gas. Record the time from concentration switching to 95 percent of final stable response. For non-extractive monitors, the highest available calibration gas concentration shall be switched into and out of the sample path and response times recorded. Perform this test sequence three (3) times. Record the results of each test on the example sheet shown in Figure 2-6.

7. Calculations, Data Analysis and Reporting.

7.1 Procedure for determination of mean values and confidence intervals.

7.1.1 The mean value of a data set is calculated according to equation 2-1.

$$\bar{x} = \frac{1}{n}\sum_{i=1}^{n} x_i \qquad \text{Equation 2-1}$$

where:

x_i = absolute value of the measurements,
Σ = sum of the individual values,
$\bar{x}$ = mean value, and
n = number of data points.

7.1.2 The 95 percent confidence interval (two-sided) is calculated according to equation 2-2:

$$C.I._{.95} = \frac{t_{.975}}{n\sqrt{n-1}}\sqrt{n\left(\sum x_i^2\right) - \left(\sum x_i\right)^2} \qquad \text{Equation 2-2}$$

where:

$\sum x_i$ = sum of all data points,
$t_{.95} = t_1 - \alpha/2$, and
C.I.$_{95}$ = 95 percent confidence interval estimate of the average mean value.

Values for $t_{.975}$

n	$t_{.975}$
2	12.706
3	4.303
4	3.182
5	2.776
6	2.571
7	2.447
8	2.365
9	2.306
10	2.262
11	2.228
12	2.201
13	2.179
14	2.160
15	2.145
16	2.131

The values in this table are already corrected for n-1 degrees of freedom. Use n equal to the number of samples as data points.

7.2 Data Analysis and Reporting.

7.2.1 Accuracy (Relative). For each of the nine reference method test points, determine the average pollutant concentration reported by the continuous monitoring system. These average concentrations shall be determined from the continuous monitoring system data recorded under 7.2.2 by integrating or averaging the pollutant concentrations over each of the time intervals concurrent with each reference method testing period. Before proceeding to the next step, determine the basis (wet or dry) of the continuous monitoring system data and reference method test data concentrations. If the bases are not constant, apply a moisture correction to either reference method concentrations or the continuous monitoring system concentrations as appropriate. Determine the correction factor by moisture tests concurrent with the reference method testing periods. Report the moisture test method and the correction procedure employed. For each of the nine test runs determine the difference for each test run by subtracting the respective reference method test concentrations (use average of each set of three measurements for NO_2) from the continuous monitoring system integrated or averaged concentrations. Using these data, compute the mean difference and the 95 percent confidence interval of the differences (equations 2-1 and 2-2). Accuracy is reported as the sum of the absolute value of the mean difference and the 95 percent confidence interval of the differences expressed as a percentage of the mean reference method value. Use the example sheet shown in Figure 2-3.

7.2.2 Calibration Error. Using the data from paragraph 6.1, subtract the measured pollutant concentration determined under paragraph 6.1.1 (Figure 2-1) from the value shown by the continuous monitoring system for each of the five readings at each concentration measured under 6.1.2 (Figure 2-2). Calculate the mean of these difference values and the 95 percent confidence intervals according to equations 2-1 and 2-2. Report the calibration error (the sum of the absolute value of the mean difference and the 95 percent confidence interval) as a percentage of each respective calibration gas concentration. Use example sheet shown in Figure 2-2.

7.2.3 Zero Drift (2-hour). Using the zero concentration values measured each two hours during the field test, calculate the differences between consecutive two-hour readings expressed in ppm. Calculate the mean difference and the confidence interval using equations 2-1 and 2-2. Report the zero drift as the sum of the absolute mean value and the confidence interval as a percentage of span. Use example sheet shown in Figure 2-4.

7.2.4 Zero Drift (24-hour). Using the zero concentration values measured every 24 hours during the field test, calculate the differences between the zero point after zero adjustment and the zero value 24 hours later just prior to zero adjustment. Calculate the mean value of these points and the confidence interval using equations 2-1 and 2-2. Report the zero drift (the sum of the absolute mean and confidence interval) as a percentage of span. Use example sheet shown in Figure 2-5.

7.2.5 Calibration Drift (2-hour). Using the calibration values obtained at two-hour intervals during the field test, calculate the differences between consecutive two-hour readings expressed as ppm. These values should be corrected for the corresponding zero drift during that two-hour period. Calculate the mean and confidence interval of these corrected difference values using equations 2-1 and 2-2. Do not use the differences between non-consecutive readings. Report the calibration drift as the sum of the absolute mean and confidence interval as a percentage of span. Use example sheet shown in in Figure 2-4.

7.2.6 Calibration Drift (24-hour). Using the calibration values measured every 24 hours during the field test, calculate the differences between the calibration concentration reading after zero and calibration adjustment, and the calibration concentration reading 24 hours later after zero adjustment but before calibration adjustment. Calculate the mean value of these differences and the confidence interval using equations 2-1 and 2-2. Report the calibration drift (the sum of the absolute mean and confidence interval) as a percentage of span. Use the example sheet shown in Figure 2-5.

7.2.7 Response Time. Using the charts from paragraph 6.3, calculate the time interval from concentration switching to 95 percent to the final stable value for all upscale and downscale tests. Report the mean of the three upscale test times and the mean of the three downscale test times. The two average times should not differ by more than 15 percent of the slower time. Report the slower

time as the system response time. Use the example sheet shown in Figure 2-6.

7.2.8 Operational Test Period. During the 168-hour performance and operational test period, the continuous monitoring system shall not require any corrective maintenance, repair, replacement, or adjustment other than that clearly specified as required in the operation and maintenance manuals as routine and expected during a one-week period. If the continuous monitoring system operates within the specified performance parameters and does not require corrective maintenance, repair, replacement or adjustment other than as specified above during the 168-hour test period, the operational period will be successfully concluded. Failure of the continuous monitoring system to meet this requirement shall call for a repetition of the 168-hour test period. Portions of the test which were satisfactorily completed need not be repeated. Failure to meet any performance specifications shall call for a repetition of the one-week performance test period and that portion of the testing which is related to the failed specification. All maintenance and adjustments required shall be recorded. Output readings shall be recorded before and after all adjustments.

Performance Specification 3—Performance specifications and specification test procedures for monitors of CO_2 and O_2 from stationary sources.

1. Principle and Applicability.

1.1 Principle. Effluent gases are continuously sampled and are analyzed for carbon dioxide or oxygen by a continuous monitoring system. Tests of the system are performed during a minimum operating period to determine zero drift, calibration drift, and response time characteristics.

1.2 Applicability. This performance specification is applicable to evaluation of continuous monitoring systems for measurement of carbon dioxide or oxygen. These specifications contain test procedures, installation requirements, and data computation procedures for evaluating the acceptability of the continuous monitoring systems subject to approval by the Administrator. Sampling may include either extractive or non-extractive (in-situ) procedures.

2. Apparatus.

2.1 Continuous Monitoring System for Carbon Dioxide or Oxygen.

2.2 Calibration Gas Mixtures. Mixture of known concentrations of carbon dioxide or oxygen in nitrogen or air. Midrange and 90 percent of span carbon dioxide or oxygen concentrations are required. The 90 percent of span gas mixture is to be used to set and check the analyzer span and is referred to as span gas. For oxygen analyzers, if the span is higher than 21 percent O_2, ambient air may be used in place of the 90 percent of span calibration gas mixture. Triplicate analyses of the gas mixture (except ambient air) shall be performed within two weeks prior to use using Reference Method 3 of this part.

2.3 Zero Gas. A gas containing less than 100 ppm of carbon dioxide or oxygen.

2.4 Data Recorder. Analog chart recorder or other suitable device with input voltage range compatible with analyzer system output. The resolution of the recorder's data output shall be sufficient to allow completion of the test procedures within this specification.

3. Definitions.

3.1 Continuous Monitoring System. The total equipment required for the determination of carbon dioxide or oxygen in a given source effluent. The system consists of three major subsystems:

3.1.1 Sampling Interface. That portion of the continuous monitoring system that performs one or more of the following operations: Delineation, acquisition, transportation, and conditioning of a sample of the source effluent or protection of the analyzer from the hostile aspects of the sample or source environment.

3.1.2 Analyzer. That portion of the continuous monitoring system which senses the pollutant gas and generates a signal output that is a function of the pollutant concentration.

3.1.3 Data Recorder. That portion of the continuous monitoring system that provides a permanent record of the output signal in terms of concentration units.

3.2 Span. The value of oxygen or carbon dioxide concentration at which the continuous monitoring system is set that produces the maximum data display output. For the purposes of this method, the span shall be set no less than 1.5 to 2.5 times the normal carbon dioxide or normal oxygen concentration in the stack gas of the affected facility.

3.3 Midrange. The value of oxygen or carbon dioxide concentration that is representative of the normal conditions in the stack gas of the affected facility at typical operating rates.

3.4 Zero Drift. The change in the continuous monitoring system output over a stated period of time of normal continuous operation when the carbon dioxide or oxygen concentration at the time for the measurements is zero.

3.5 Calibration Drift. The change in the continuous monitoring system output over a stated time period of normal continuous operation when the carbon dioxide or oxygen continuous monitoring system is measuring the concentration of span gas.

3.6 Operational Test Period. A minimum period of time over which the continuous monitoring system is expected to operate within certain performance specifications without unscheduled maintenance, repair, or adjustment.

3.7 Response time. The time interval from a step change in concentration at the input to the continuous monitoring system to the time at which 95 percent of the corresponding final value is displayed on the continuous monitoring system data recorder.

4. Installation Specification.

Oxygen or carbon dioxide continuous monitoring systems shall be installed at a location where measurements are directly representative of the total effluent from the affected facility or representative of the same effluent sampled by a SO_2 or NO_x continuous monitoring system. This requirement shall be complied with by use of applicable requirements in Performance Specification 2 of this appendix as follows:

4.1 Installation of Oxygen or Carbon Dioxide Continuous Monitoring Systems Not Used to Convert Pollutant Data. A sampling location shall be selected in accordance with the procedures under paragraphs 4.2.1 or 4.2.2, or Performance Specification 2 of this appendix.

4.2 Installation of Oxygen or Carbon Dioxide Continuous Monitoring Systems Used to Convert Pollutant Continuous Monitoring System Data to Units of Applicable Standards. The diluent continuous monitoring system (*oxygen or carbon dioxide*) shall be installed at a sampling location where measurements that can be made are representative of the effluent gases sampled by the pollutant continuous monitoring system(s). Conformance with this requirement may be accomplished in any of the following ways:

4.2.1 The sampling location for the diluent system shall be near the sampling location for the pollutant continuous monitoring system such that the same approximate point(s) (extractive systems) or path (in-situ systems) in the cross section is sampled or viewed.

4.2.2 The diluent and pollutant continuous monitoring systems may be installed at different locations if the effluent gases at both sampling locations are nonstratified as determined under paragraphs 4.1 or 4.3, Performance Specification 2 of this appendix and there is no in-leakage occurring between the two sampling locations. If the effluent gases are stratified at either location, the procedures under paragraph 4.2.2, Performance Specification 2 of this appendix shall be used for installing continuous monitoring systems at that location.

5. Continuous Monitoring System Performance Specifications.

The continuous monitoring system shall meet the performance specifications in Table 3–1 to be considered acceptable under this method.

6. Performance Specification Test Procedures.

The following test procedures shall be used to determine conformance with the requirements of paragraph 4. Due to the wide variation existing in analyzer designs and principles of operation, these procedures are not applicable to all analyzers. Where this occurs, alternative procedures, subject to the approval of the Administrator, may be employed. Any such alternative procedures must fulfill the same purposes (verify response, drift, and accuracy) as the following procedures, and must clearly demonstrate conformance with specifications in Table 3–1.

6.1 Calibration Check. Establish a calibration curve for the continuous monitoring system using zero, midrange, and span concentration gas mixtures. Verify that the resultant curve of analyzer reading compared with the calibration gas value is consistent with the expected response curve as described by the analyzer manufacturer. If the expected response curve is not produced, additional calibration gas measurements shall be made, or additional steps undertaken to verify the accuracy of the response curve of the analyzer.

6.2 Field Test for Zero Drift and Calibration Drift. Install and operate the continuous monitoring system in accordance

with the manufacturer's written instructions and drawings as follows:

TABLE 3–1.—*Performance specifications*

Parameter	*Specification*
1. Zero drift (2 h) [1]	≤0.4 pct O_2 or CO_2.
2. Zero drift (24 h) [1]	≤0.5 pct O_2 or CO_2.
3. Calibration drift (2 h) [1]	≤0.4 pct O_2 or CO_2.
4. Calibration drift (24 h) [1]	≤0.5 pct O_2 or CO_2.
5. Operational period	168 h minimum.
6. Response time	10 min.

[1] Expressed as sum of absolute mean value plus 95 pct confidence interval of a series of tests.

6.2.1 Conditioning Period. Offset the zero setting at least 10 percent of span so that negative zero drift may be quantified. Operate the continuous monitoring system for an initial 168-hour conditioning period in a normal operational manner.

6.2.2. Operational Test Period. Operate the continuous monitoring system for an additional 168-hour period maintaining the zero offset. The system shall monitor the source effluent at all times except when being zeroed, calibrated, or backpurged.

6.2.3 Field Test for Zero Drift and Calibration Drift. Determine the values given by zero and midrange gas concentrations at two-hour intervals until 15 sets of data are obtained. For non-extractive continuous monitoring systems, determine the zero value given by a mechanically produced zero condition or by computing the zero value from upscale measurements using calibrated gas cells certified by the manufacturer. The midrange checks shall be performed by using certified calibration gas cells functionally equivalent to less than 50 percent of span. Record these readings on the example sheet shown in Figure 3–1. These two-hour periods need not be consecutive but may not overlap. In-situ CO, or O_2 analyzers which cannot be fitted with a calibration gas cell may be calibrated by alternative procedures acceptable to the Administrator. Zero and calibration corrections and adjustments are allowed only at 24-hour intervals or at such shorter intervals as the manufacturer's written instructions specify. Automatic corrections made by the continuous monitoring system without operator intervention or initiation are allowable at any time. During the entire 168-hour test period, record the values given by zero and span gas concentrations before and after adjustment at 24-hour intervals in the example sheet shown in Figure 3–2.

6.3 Field Test for Response Time.

6.3.1 Scope of Test.

This test shall be accomplished using the continuous monitoring system as installed, including sample transport lines if used. Flow rates, line diameters, pumping rates, pressures (do not allow the pressurized calibration gas to change the normal operating pressure in the sample line), etc., shall be at the nominal values for normal operation as specified in the manufacturer's written instructions. If the analyzer is used to sample more than one source (stack), this test shall be repeated for each sampling point.

6.3.2 Response Time Test Procedure.

Introduce zero gas into the continuous monitoring system sampling interface or as close to the sampling interface as possible. When the system output reading has stabilized, switch quickly to a known concentration of gas at 90 percent of span. Record the time from concentration switching to 95 percent of final stable response. After the system response has stabilized at the upper level, switch quickly to a zero gas. Record the time from concentration switching to 95 percent of final stable response. Alternatively, for nonextractive continuous monitoring systems, the highest available calibration gas concentration shall be switched into and out of the sample path and response times recorded. Perform this test sequence three (3) times. For each test, record the results on the data sheet shown in Figure 3–3.

7. Calculations, Data Analysis, and Reporting.

7.1 Procedure for determination of mean values and confidence intervals.

7.1.1 The mean value of a data set is calculated according to equation 3–1.

$$\bar{x} = \frac{1}{n}\sum_{i=1}^{n} x_i \qquad \text{Equation 3–1}$$

where:

x_i = absolute value of the measurements,
Σ = sum of the individual values,
$\bar{x}$ = mean value, and
n = number of data points.

7.2.1 The 95 percent confidence interval (two-sided) is calculated according to equation 3–2:

$$C.I._{95} = \frac{t_{.975}}{n\sqrt{n-1}}\sqrt{n(\sum x_i^2) - (\sum x_i)^2} \qquad \text{Equation 3–2}$$

where:

ΣX = sum of all data points,
$t_{.975} = t_{1-\alpha/2}$, and
$C.I._{95}$ = 95 percent confidence interval estimates of the average mean value.

Values for $t_{.975}$

n	$t_{.975}$
2	12.706
3	4.303
4	3.182
5	2.776
6	2.571
7	2.447
8	2.365
9	2.306
10	2.262
11	2.228
12	2.201
13	2.179
14	2.160
15	2.145
16	2.131

The values in this table are already corrected for n-1 degrees of freedom. Use n equal to the number of samples as data points.

7.2 Data Analysis and Reporting.

7.2.1 Zero Drift (2-hour). Using the zero concentration values measured each two hours during the field test, calculate the differences between the consecutive two-hour readings expressed in ppm. Calculate the mean difference and the confidence interval using equations 3-1 and 3-2. Record the sum of the absolute mean value and the confidence interval on the data sheet shown in Figure 3-1.

7.2.2 Zero Drift (24-hour). Using the zero concentration values measured every 24 hours during the field test, calculate the differences between the zero point after zero adjustment and the zero value 24 hours later just prior to zero adjustment. Calculate the mean value of these points and the confidence interval using equations 3-1 and 3-2. Record the zero drift (the sum of the absolute mean and confidence interval) on the data sheet shown in Figure 3-2.

7.2.3 Calibration Drift (2-hour). Using the calibration values obtained at two-hour intervals during the field test, calculate the differences between consecutive two-hour readings expressed as ppm. These values should be corrected for the corresponding zero drift during that two-hour period. Calculate the mean and confidence interval of these *corrected difference* values using equations 3-1 and 3-2. Do not use the differences between non-consecutive readings. Record the sum of the absolute mean and confidence interval upon the data sheet shown in Figure 3-1.

7.2.4 Calibration Drift (24-hour). Using the calibration values measured every 24 hours during the field test, calculate the differences between the calibration concentration reading after zero and calibration adjustment and the calibration concentration reading 24 hours later after zero adjustment but before calibration adjustment. Calculate the mean value of these differences and the confidence interval using equations 3-1 and 3-2. Record the sum of the absolute mean and confidence interval on the data sheet shown in Figure 3-2.

7.2.5 Operational Test Period. During the 168-hour performance and operational test period, the continuous monitoring system shall not receive any corrective maintenance, repair, replacement, or adjustment other than that clearly specified as required in the manufacturer's written operation and maintenance manuals as routine and expected during a one-week period. If the continuous monitoring system operates within the specified *performance parameters* and does not require corrective maintenance, repair, replacement or adjustment other than as specified above during the 168-hour test period, the operational period will be successfully concluded. Failure of the continuous monitoring system to meet this requirement shall call for a repetition of the 168 hour test period. Portions of the test which were satisfactorily completed need not be repeated. Failure to meet any performance specifications shall call for a repetition of the one-*week* performance test period and that portion of the testing which is related to the failed specification. All maintenance and adjustments required shall be recorded. Output readings shall be recorded before and after all adjustments.

7.2.6 Response Time. Using the data developed under paragraph 6.3, calculate the time interval from concentration switching to 95 percent to the final stable value for all upscale and downscale tests. Report the mean of the three upscale test times and the mean of the three downscale test times. The two average times should not differ by more than 15 percent of the slower time. Report the slower time as the system response time. Record the results on Figure 3-3.

Appendix C—Determination of Emission Rate Change

1. *Introduction.*

1.1 The following method shall be used to determine whether a physical or operational change to an existing facility resulted in an increase in the emission rate to the atmosphere. The method used is the Student's *t* test, commonly used to make inferences from small samples.

2. *Data.*

2.1 Each emission test shall consist of *n* runs (usually three) which produce *n* emission rates. Thus two sets of emission rates are generated, one before and one after the change, the two sets being of equal size.

2.2 When using manual emission tests, except as provided in § 60.8(b) of this part, the reference methods of Appendix A to this part shall be used in accordance with the procedures specified in the applicable subpart both before and after the change to obtain the data.

2.3 When using continuous monitors, the facility shall be operated as if a manual emission test were being performed. Valid data using the averaging time which would be required if a manual emission test were being conducted shall be used.

3. *Procedure.*

3.1 Subscripts *a* and *b* denote prechange and postchange respectively.

3.2 Calculate the arithmetic mean emission rate, $\bar{E}$, for each set of data using Equation 1.

$$\bar{E} = \sum_{i=1}^{n} \frac{E_i}{n} = \frac{E_1 + E_2 \ldots + E_n}{n} \quad (1)$$

where:

E_i = Emission rate for the *i* th run.

n = number of runs

3.3 Calculate the sample variance, S^2, for each set of data using Equation 2.

$$S^2 = \frac{\sum_{i=1}^{n} (E_i - \bar{E})^2}{n-1} = \frac{\sum_{i=1}^{n} E_i^2 - \left(\sum_{i=1}^{n} E_i\right)^2 \Big/ n}{n-1} \quad (2)$$

3.4 Calculate the pooled estimate, S_p, using Equation 3.

$$S_p = \left[\frac{(n_a - 1)\, S_a^2 + (n_b - 1)\, S_b^2}{n_a + n_b - 2}\right]^{1/2} \quad (3)$$

3.5 Calculate the test statistic, *t*, using Equation 4.

APPENDIX E

SUMMARY OF PREVIOUS DATA FROM SITE 2

Location No. 18, Test No. 9

Boiler No. 2 at Location 18 is a Babcock and Wilcox integral furnace watertube boiler with a rated capacity of 90,000 lbs/hr steam flow and was installed in 1935. The current top load capability is 79,000 lbs/hr steam flow and is limited by the fans. The furnace wall consists of watertubes approximately 3 inches in diameter spaced 10.25 inches on centers. The wall exposure between the tubes consists of refractory; the furnace was rebricked in 1972. The boiler operates at a nominal steam pressure of 320 psig and steam temperature of 428°F (saturation).

Three B&W steam-atomized burners are spaced in a triangular pattern, with the top burner spaced directly above the center position of the lower two burners. The vertical spacing (height of the triangle) is 36 inches, and the horizontal spacing (base of the triangle) is 37 inches. The oil guns use a B&W Y-jet steam atomizer with the steam pressure at the burner nominally 35 psi greater than the oil pressure. No. 6 fuel oil was used for this test. The temperature of the oil at the burner varied from 185°F at the lower loads to 208°F at top load. The oil pressure at the burner at top load was 85 psig. A tubular type preheater is used to preheat the combustion air; however, no air temperature data were available during this test.

The furnace volume and area loading, i.e., ft^3/MBtu/hr and ft^2/MBtu/hr, and burner loading are all about average for boilers of this capacity.

The NO_x emissions and excess O_2 levels as a function of boiler steam flow are presented in Figure E-1. Although the O_2 levels are high over the entire load range investigated, there is not the sharp increase in O_2 at lower loads which has typically caused the emissions from other boilers to increase at lower loads. This practice of holding the excess oxygen relatively constant over the load range is unique to location 18 boilers and is followed consistently at most facilities of the same company.

Maximum NO_x levels were found to occur at baseline to top load operating conditions. The effect of excess O_2 on NO_x emissions is presented in Figure E-2 and shows a relatively strong effect, especially for the high operating excess

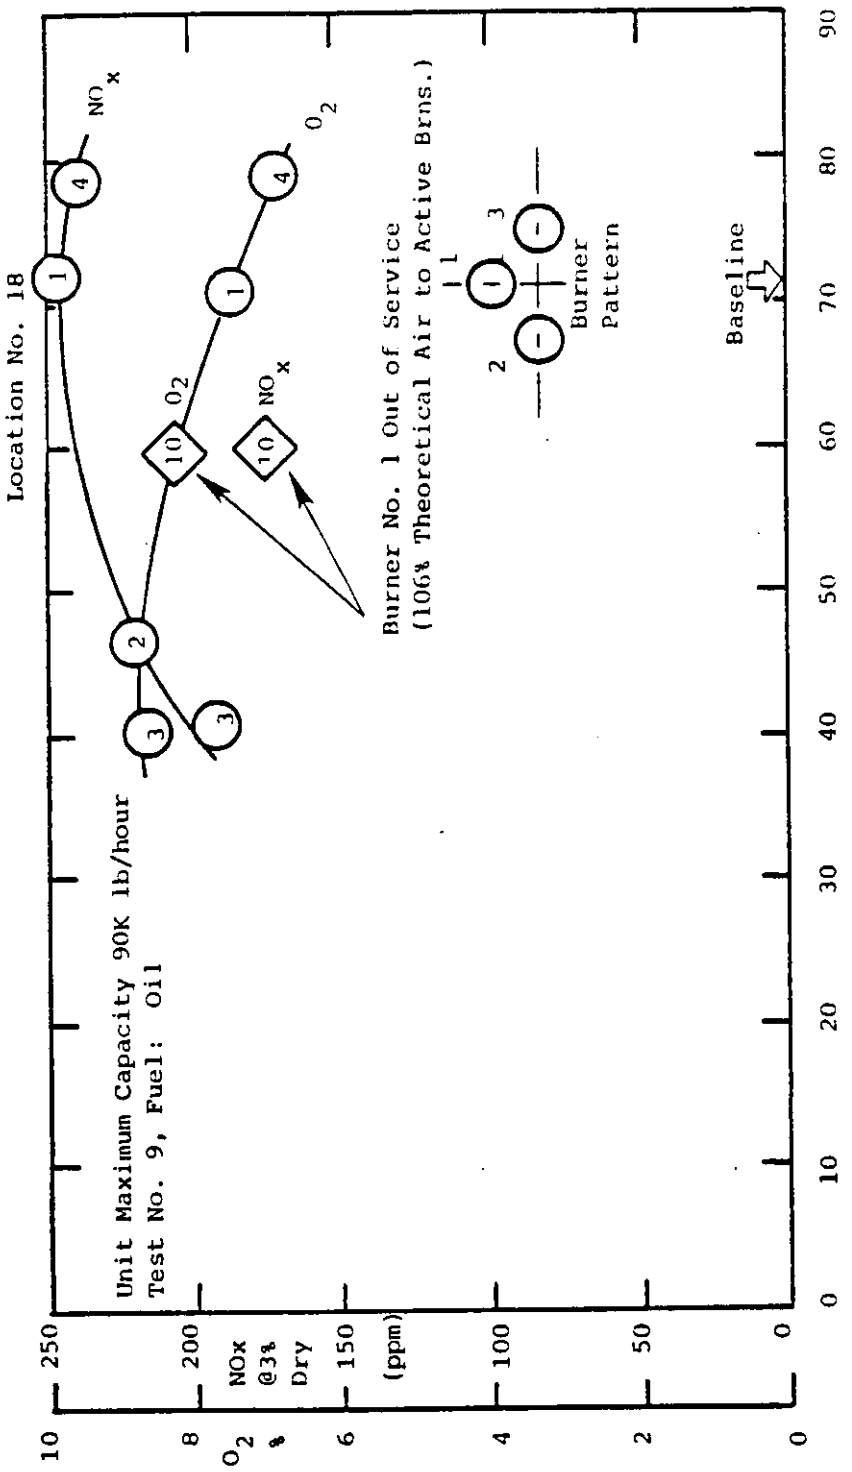

Figure E-1. Effect of Load

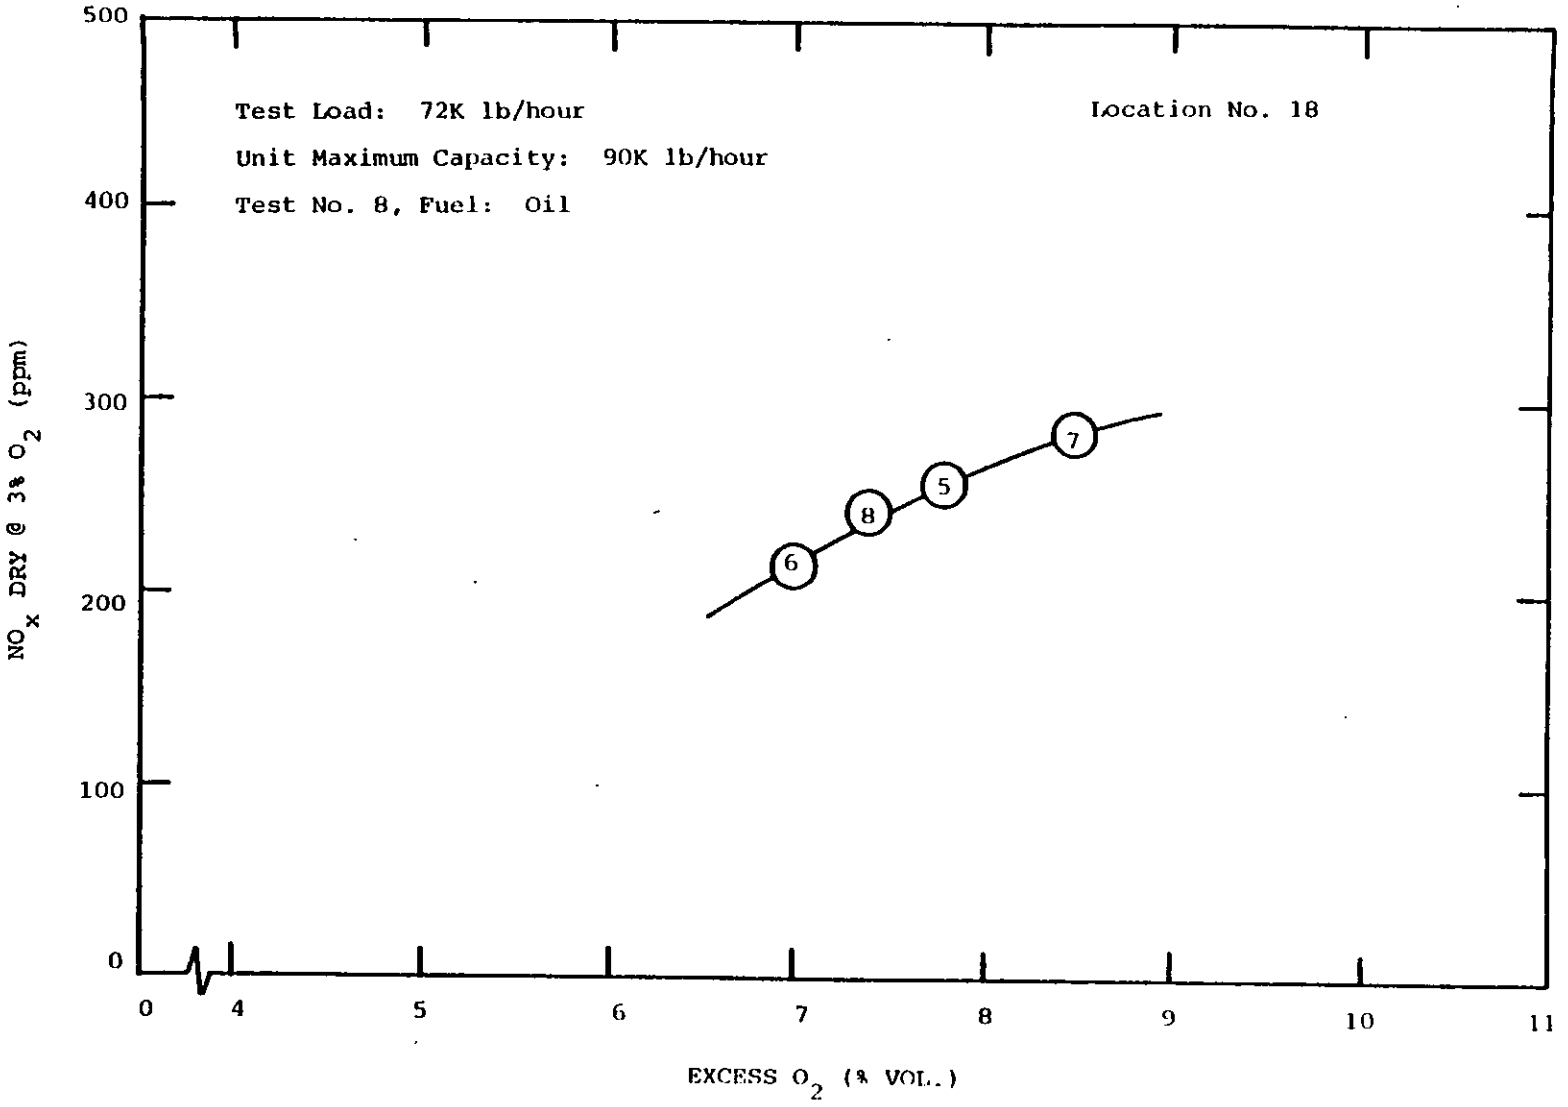

Figure E-2. Effect of Excess Oxygen

O_2 levels. Since the furnace pressure is slightly negative, air may be leaking into the flue passes through the boiler casing into the backpasses and flue duct, such that the O_2 levels in the furnace may be substantially lower than those measured downstream at the sampling port.

The burner pattern previously described offered the opportunity of experimenting with off-stoichiometric combustion by removing the center burner (No. 1). This did not upset the symmetry of the furnace because of the triangular arrangement of the burners. Figure E-1 presents the NO_x and O_2 data for this test. By terminating the fuel flow to the No. 1 burner and leaving the air registers 100 percent open, the excess air to the active burners was reduced to two-thirds of its original value with all burners in service, because the remaining one-third of the air was injected through the out-of-service burner port. This test was conducted at 60,000 lbs/hr steam flow and an excess O_2 level of 8.2 percent. Assuming the excess O_2 levels measured in the flue duct are representative of the air flow through the burners, the percent theoretical air at the burner was reduced from 162 percent to 106 percent. The NO_x emissions were reduced from 240 ppm to 175 ppm or a reduction of 27 percent.

Sulfur oxide concentrations for the baseline operating condition were found to be 485 ppm of total SO_x with 465 ppm of SO_2. The ratio of SO_3/SO_x for this test is 4 percent and the range of data obtained for this SO_x concentration is from 2 percent to 5 percent. Particulate emissions of 0.134 lbs/10^6 Btu were measured for the baseline operating condition which is about average for steam-atomized No. 6 fuel oil tests.

TECHNICAL REPORT DATA (Please read Instructions on the reverse before completing)		
1. REPORT NO. EPA-600/7-80-085b	2.	3. RECIPIENT'S ACCESSION NO.
4. TITLE AND SUBTITLE Thirty-day Field Tests of Industrial Boilers: Site 2--Residual-oil-fired Boiler		5. REPORT DATE April 1980 6. PERFORMING ORGANIZATION CODE
7. AUTHOR(S) W.A. Carter and R.J. Tidona		8. PERFORMING ORGANIZATION REPORT NO.
9. PERFORMING ORGANIZATION NAME AND ADDRESS KVB, Inc. P.O. Box 19618 Irvine, California 92714		10. PROGRAM ELEMENT NO. EHE624 11. CONTRACT/GRANT NO. 68-02-2645, Task 4
12. SPONSORING AGENCY NAME AND ADDRESS EPA, Office of Research and Development Industrial Environmental Research Laboratory Research Triangle Park, NC 27711		13. TYPE OF REPORT AND PERIOD COVERED Task Final; 3/79-3/80 14. SPONSORING AGENCY CODE EPA/600/13

15. SUPPLEMENTARY NOTES IERL-RTP project officer is Robert E. Hall, Mail Drop 65, 919/541-2477.

16. ABSTRACT This report is a final one for a test program to evaluate the long-term effectiveness of combustion modifications on industrial boilers. Previous short-term tests had been performed on industrial boilers to determine the effect of combustion modifications on such air pollutant emissions as NOx, SOx, CO, HC, and particulate. The objective of this program was to determine if the combustion modification techniques which were effective for the short-term tests are feasible for longer periods. The report gives results of a 30-day field test of a 26.4 MW output (90,000 lb steam/hr) residual-oil-fired boiler using staged combustion air and low excess air to control NOx emissions. Results indicate that these combustion modifications are effective long-term NOx controls for this type of residual-oil-fired boiler. The as-found NOx concentration was 158 ng/J (281 ppm at 3% O2, dry). With staged combustion and low excess air firing, the mean NOx emission level was 110 ng/J (196 ppm at 3% O2, dry). Boiler efficiency increased by 0.7% under low NOx firing conditions.

17. KEY WORDS AND DOCUMENT ANALYSIS				
a. DESCRIPTORS		b. IDENTIFIERS/OPEN ENDED TERMS	c. COSATI Field/Group	
Pollution	Carbon Monoxide	Pollution Control	13B	
Boilers	Hydrocarbons	Stationary Sources	13A	07C
Residual Oils	Dust	Industrial Boilers	21D	11G
Combustion		Combustion Modification	21B	
Field Tests		Staged Combustion	14B	
Sulfur Oxides		Low Excess Air	07B	
Nitrogen Oxides		Particulate
